# Positive theories of HNN-extensions and amalgamated free products 

Markus Lohrey<br>Universität Stuttgart, FMI, Germany<br>lohrey@informatik.uni-stuttgart.de<br>Géraud Sénizergues<br>Université Bordeaux I, LaBRI, France<br>ges@labri.u-bordeaux.fr

#### Abstract

It is shown that the positive first-order theory of an HNN-extension $G=\left\langle H, t ; t^{-1} a t=\varphi(a)(a \in A)\right\rangle$ can be reduced to the existential firstorder theory of $G$ provided that $A$ and $B$ are proper subgroups of the base group $H$ with $A \cap B$ finite. For an amalgamated free product $G=H *_{A} J$, we show that the positive first-order theory of $G$ can be reduced to the existential first-order theory of $G$ in case $A$ is finite.

## 1 Introduction

This paper is the third paper in a serious of papers on equations over HNNextensions and amalgamated free products. These two operations are of fundamental importance in combinatorial group theory [15]. Recall that an amalgamated free product

$$
\begin{equation*}
G=H *_{A} J \tag{1}
\end{equation*}
$$

of two groups $H$ and $J$, where $A$ is a subgroup of $H$ and $J$ and $A=H \cap J$, results from the free product $H * J$ by identifying every element of $A \leq H$ with its corresponding element in $A \leq J$. An HNN extension

$$
\begin{equation*}
G=\left\langle H, t ; t^{-1} a t=\varphi(a)(a \in A)\right\rangle \tag{2}
\end{equation*}
$$

of a group $H$, where $A$ and $B$ are isomorphic subgroups of $H$ and $\varphi: A \rightarrow B$ is an isomorphism, results from adding to $H$ a new generator $t$ such that the conjugation of the subgroup $A \leq H$ by $t$ equals the isomorphism $\varphi$.

In [14] we proved several decidability results for algorithmic problems for rational subsets in HNN-extensions and amalgamated free products. Based on theses results, we continued our investigations with existential theories of equations (together with additional constraints for variables) in HNN-extensions
and amalgamated free products [13]. Equations over groups and also monoids are a classical research topic at the borderline between algebra, mathematical logic, and theoretical computer science. This line of research was initiated by the work of Lyndon, Tarksi, and others in the first half of the 20th century. For a given group $G$, we are mainly concerned with two theories associated with $G$ : (i) the existential theory of $G$ contains all true statements about $G$ of the form $\exists x_{1} \in G \cdots \exists x_{n} \in G: \varphi$, where $\varphi$ is a boolean combination of equations over $G$. The left- and right hand sides of these equations are products of elements from the group $G$ as well as variables $x_{i}$ and their inverses. The positive theory of $G$ consists of all true statements about $G$, where also universally quantified variables are allowed, but the use of negations is forbidden, i.e., conjunction and disjunction are the only allowed boolean connectives.

Basically, Merzlyakov has shown that the positive theory of a free group can be reduced to the existential theory of another free group [19], see also [11]. Toghether with the later result of Makanin concerning the decidability of the existential theory of a free group [16, 17], this shows that every free group has a decidable positive theory [17]. This result is an important step in the recent proof of Tarski's conjecture by Kharlampovich and Myasnikov, namely that the full first-order theory of a free group is decidable [12]. Roughly speaking, Merzlyakov proved that a positive sentence $\psi$, which is interpreted in a free group $F$, is equivalent to the existential sentence $\theta$ that results from $\psi$ by replacing its universally quantified variables $x_{1}, \ldots, x_{n}$ by new constants $k_{1}, \ldots, k_{n}$. These new constants do not interact with the free group $F$, i.e., the resulting sentence $\theta$ is interpreted in the free product $F * F\left(k_{1}, \ldots k_{n}\right)$ (where $F\left(k_{1}, \ldots k_{n}\right)$ is the free group generated by $\left.k_{1}, \ldots k_{n}\right)$, which is again a free group.

Merzlyakov's technique was recently extended to larger classes of groups: [6] deals with graph products of free and finite groups and [10] considers groups with a free regular length function. In [5] a general transfer theorem for positive theories was shown for graph products: under some algebraic restrictions, the decidability of the existential theory of a graph product implies the decidability of the positive theory of the graph product. Graph products are a well-known mathematical construction that generalize both free and direct products, see e.g. [9].

In this paper we adapt Merzlyakov's technique to certain HNN-extensions and amalgamated free products. In order to do this for an HNN-extension $G=\left\langle H, t ; t^{-1} a t=\varphi(a)(a \in A)\right\rangle$, we have to assume that $A$ and $B=\varphi(A)$ have finite intersection. In this situation, we are again able to replace the universally quantified variables $x_{1}, \ldots, x_{n}$ of a positive sentence $\psi$ by new constants $k_{1}, \ldots, k_{n}$. But unlike for the case of a free group, we cannot avoid some interaction between these new constants and the group $G$. More precisely, there exists a (necessarily finite) subgroup $X \subseteq A \cap B \leq G$ such that for every $1 \leq i \leq n$ we have to impose the defining relation $k_{i}^{-1} a k_{i}=f_{i}(a)(a \in X)$ for some automorphism $f_{i}: X \rightarrow X$. Thus, the existential sentence $\theta$ that results from $\psi$ by replacing the universally quantified variable $x_{i}$ by the constant $k_{i}$ is interpreted in a multiple HNN-extension $\mathbb{G}$ of $G$, where in each single HNN-extension the
finite subgroup $X$ is associated with itself. Finally we can apply [13, ] in order to reduce the existential theory of the this HNN-extension $\mathbb{G}$ to the existential theory of the initial HNN-extension $G$. This shows that for an HNN-extension $G=\left\langle H, t ; t^{-1} a t=\varphi(a)(a \in A)\right\rangle$ with $A \cap \varphi(A)$ finite, the positive theory of $G$ is decidable if the existential theory of $G$ is decidable (Theorem 3.1). Similarly, for an amalgamated free products $G=H *_{A} J$, where $A$ is finite, we show that the positive theory of $G$ is decidable if the existential theory of $G$ is decidable (Theorem 4.1). Finally, from Theorem 3.1, 4.1, and [13, ], we can easily deduce that every virtually free group (i.e., a group with a free subgroup of finite index) has a decidable positive theory. This result relies on the fact that every virtually free group can be built up from finite groups using the operations of amalgamated free products and HNN-extensions, both subject to the finiteness restrictions above, see e.g. [4].

## 2 Preliminaries

For sets $A$ and $B$ we write $f: A \rightarrow_{p} B$ in order to express that $f$ is a partial mapping from $A$ to $B$. For $C \subseteq A$ we denote by $f \upharpoonright_{C}$ the restriction of $f$ to $C$. The identity function on a set $A$ is denoted by $\mathrm{id}_{A}$.

Let us fix a group $G$. Formulas of first-order logic over $G$ are built up from atomic formulas of the form $x y=z, x^{-1}=y$, and $x=g$ (where $x$ and $y$ are variables ranging over elements of $G$, and $g \in G$ is a constant) using boolean connectives and quantifications over variables. A boolean formula is a formula without quantifiers. A formula $\varphi$ is called positive if there are no negations in $\varphi$, i.e., it is built up from conjunctions, disjunctions and (universal and existential) quantifiers. A formula $\varphi$ is called existential (resp. existential positive) if it is of the form $\exists x_{1} \cdots \exists x_{n}: \psi\left(x_{1}, \ldots, x_{n}\right)$, where $\psi$ is a boolean (resp. positive boolean) combination of atomic formulas. For $G$ countable, we denote with $\mathrm{Th}_{\exists}(G)$ (resp. $\left.\mathrm{Th}_{+}(G), \mathrm{Th}_{\exists+}(G)\right)$ the set of all existential (resp. positive, existential positive) sentences that are true in $G$, this set is countable again. For a countable set $\mathcal{C} \subseteq 2^{G}$ of constraints we denote with $\operatorname{Th}_{\exists}(G, \mathcal{C})$ the extension of $\operatorname{Th}_{\exists}(G)$, where also atomic formulas of the form $x \in L$ for $L \in \mathcal{C}$ are allowed. We restrict here to a countable $G$ and a countable $\mathcal{C}$, in order to ensure that the above theories are countable. Hence, it makes sense to ask for the decidability of these theories. We will use the following result from [13]:

Theorem 2.1. Let $H$ be a group and let $A$ be a finite subgroup of $H$. Let $\mathcal{C}=\left\{B_{i} \mid i \in I\right\}$ be a class of constraints in $H$, where every $B_{i}$ is a subgroup of $H$, which contains $A$. Let $G=\left\langle H, t ; t^{-1} a t=\varphi(a)(a \in A)\right\rangle$ be an HNNextension of $H$, where $\varphi: A \rightarrow A$ is an automorphism of $A$. For every $i \in I$ let $C_{i}$ be the subgroup of $G$ generated by $B_{i}$ and the stable letter $t$. Let $\mathcal{D}=$ $\left\{B_{i} \mid i \in I\right\} \cup\left\{C_{i} \mid i \in I\right\}$ If $\operatorname{Th}_{\exists+}(H, \mathcal{C})$ is decidable, then also $\mathrm{Th}_{\exists+}(G, \mathcal{D})$ is decidable.

For a subgroup $X$ of $G$, we denote with $\operatorname{In}(X, G)$ the group of all automorphisms $f$ of $X$ such that for some $g \in G$ we have: $f(x)=g^{-1} x g$ for all $x \in X$.

The notation $\operatorname{In}(X, G)$ is intended to refer to the inner automorphism group $\operatorname{In}(X)=\operatorname{In}(X, X)$ of $X$.

## 3 HNN-extensions

In this section we consider positive theories of HNN-extensions. Let us fix throughout this section a group $H$ (the base group), two proper subgroups $A<H, B<H$ and an isomorphism $\varphi: A \rightarrow B$. The subgroups $A$ and $B$ are not necessarily finite. Let

$$
G=\left\langle H, t ; t^{-1} a t=\varphi(a)(a \in A)\right\rangle
$$

be the corresponding HNN-extension. The aim of this section is to prove the following result:

Theorem 3.1. Let $G=\left\langle H, t ; t^{-1}\right.$ at $\left.=\varphi(a)(a \in A)\right\rangle$ be an HNN-extension, where $A$ and $B$ are proper subgroups of $H$ with $A \cap B$ finite. If $\operatorname{Th}_{\exists+}(G)$ is decidable, then also $\mathrm{Th}_{+}(G)$ is decidable.

Remark 3.2. Theorem 3.1 can be slightly generalized by only assuming that for some $h \in H, h^{-1} A h \cap B$ is finite, because by applying a Tietze transformation [15], which replaces $t$ by ht, this case can be reduced to the case that $A \cap B$ is finite.

### 3.1 Reduced $t$-sequences

Recall from [14] that a $t$-sequence is an element from the free product $H *$ $\left\{t, t^{-1}\right\}^{*}$. A $t$-sequence is reduced if it does not contain a factor from Forbid $=$ $\left\{t^{-1} a t \mid a \in A\right\} \cup\left\{t b t^{-1} \mid b \in B\right\}$. Alternatively, we can view a reduced $t$ sequence as a word from the language $\operatorname{Red}(H, t)=\left(\left(H\left\{t, t^{-1}\right\}\right)^{*} H\right) \backslash \Gamma^{*} \operatorname{Forbid} \Gamma^{*}$, where $\Gamma=H \cup\left\{t, t^{-1}\right\}$. Usually, we omit a factor 1 in a reduced $t$-sequence, e.g., we identify the reduced $t$-sequence $1 t 1 t 1$ with the word $t t$. For $u, v, w \in$ $\operatorname{Red}(H, t)$ we write $u \cdot v=w$ if and only if $u v=w$ as words over the alphabet $\Gamma$. Note that this implies that we cannot have $u \in \Gamma^{*}(H \backslash\{1\})$ and $v \in(H \backslash\{1\}) \Gamma^{*}$ at the same time. In this case, we also say that the concatenation $u \cdot v$ of $u$ and $v$ is defined

With $\sim$ we denote the smallest congruence on $H *\left\{t, t^{-1}\right\}^{*}$ containing all pairs $\left(t, a^{-1} t \varphi(a)\right)$ for $a \in A$ and $\left(t^{-1}, b^{-1} t^{-1} \varphi^{-1}(b)\right)$ for $b \in B$. Then $u, v \in$ $\operatorname{Red}(H, t)$ represent the same element of the HNN-extension $G$ if and only if $u \sim v$ [14]. Equivalently, if

$$
\begin{align*}
u & =h_{0} t^{\alpha_{1}} h_{1} t^{\alpha_{2}} \cdots h_{n-1} t^{\alpha_{n}} h_{n} \text { and }  \tag{3}\\
v & =k_{0} t^{\beta_{1}} k_{1} t^{\beta_{2}} \cdots k_{m-1} t^{\beta_{m}} k_{m} \tag{4}
\end{align*}
$$

(with $n, m \geq 0, \alpha_{1}, \ldots, \alpha_{n}, \beta_{1}, \ldots, \beta_{m} \in\{1,-1\}$ and $h_{0}, \ldots h_{n}, k_{0}, \ldots, k_{m} \in H$ ) are reduced $t$-sequences, then $u \sim v$ if and only if $n=m, \alpha_{i}=\beta_{i}$ for $1 \leq i \leq n$, and there exist $c_{1}, \ldots, c_{2 n} \in A \cup B$ such that:

- if $\alpha_{i}=1$ then $c_{2 i-1} \in A$ and $c_{2 i}=\varphi\left(c_{2 i-1}\right) \in B(1 \leq i \leq n)$
- if $\alpha_{i}=-1$ then $c_{2 i} \in A$ and $c_{2 i-1}=\varphi\left(c_{2 i}\right) \in B(1 \leq i \leq n)$
- $h_{i} c_{2 i+1}=c_{2 i} k_{i}$ in $H$ for $0 \leq i \leq n$ (here we set $c_{0}=c_{2 n+1}=1$ )

This situation can be visualized by a diagram of the following form (also called a Van Kampen diagram, see [15] for more details):

Note that if $e_{i}=1$ (resp. $e_{i}=-1$ ), then we must have $c_{2 i-1} \in A$ and $c_{2 i} \in B$ (resp. $c_{2 i-1} \in B$ and $c_{2 i} \in A$ ).

In Section 3.4 we will reason a lot with diagrams of the above form. The elements $c_{i}$ are also called the connecting elements. Sometimes we will also omit in diagrams some of the connecting elements. The two paths between the leftmost and the rightmost point in the above diagram are also called the upper and lower bow, respectively. An interval on one of these bows is called a segment.

For the above $u \in \operatorname{Red}(H, t)$ in (3) define $\pi_{t}(u)=t^{\alpha_{1}} t^{\alpha_{2}} \cdots t^{\alpha_{n}}$, $u^{-1}=$ $h_{n}^{-1} t^{-\alpha_{n}} h_{n-1}^{-1} \cdots t^{-\alpha_{2}} h_{1}^{-1} t^{-\alpha_{1}} h_{0}^{-1}$, and $|u|=n$. Note that $|u|$ is not the length of $u$ as a word over $\Gamma=H \cup\left\{t, t^{-1}\right\}$ but only the number of occurrences of $t$ and $t^{-1}$ in $u$. This definition has the advantage that $u \sim v$ implies $|u|=|v|$ for $u, v \in \operatorname{Red}(H, t)$. In fact, $u \sim v$ even implies $\pi_{t}(u)=\pi_{t}(v)$.

In the following, we identify the set $\operatorname{Red}(H, t)$ with the relational structure that contains the following predicates and constants:

- the ternary relation $\{(u, v, w) \mid u \cdot v \sim w\}$
- the ternary relation $\{(u, v, w) \mid u, v, w \in H, u v=w$ in $H\}$
- the binary relation $\left\{(u, v) \mid u \sim v^{-1}\right\}$
- every element of $\operatorname{Red}(H, t)$ as a constant

We will use the following lemma from [13]:
Lemma 3.3. For a given boolean combination $\phi\left(x_{1}, \ldots, x_{n}\right)$ of word equations over the $H N N$-extension $G$ we can effectively construct an existential formula $\exists y_{1} \cdots \exists y_{m}: \chi\left(x_{1}, \ldots, x_{n}, y_{1}, \ldots, y_{m}\right)$ over the structure $\operatorname{Red}(H, t)$ such that for all $s_{1}, \ldots, s_{n} \in \operatorname{Red}(H, t)$ we have:

$$
\phi\left(s_{1}, \ldots, s_{n}\right) \text { in } G \quad \Leftrightarrow \quad \exists y_{1} \cdots \exists y_{m}: \chi\left(s_{1}, \ldots, s_{n}, y_{1}, \ldots, y_{m}\right) \text { in } \operatorname{Red}(H, t)
$$

(here, when writing $\phi\left(s_{1}, \ldots, s_{n}\right)$ in $G$, we identify $s_{i} \in \operatorname{Red}(H, t)$ with the element from $G$ it represents).

### 3.2 The finite normal subgroup $X$ and stabilizing sequences

For a (necessarily finite) subgroup $X \leq A \cap B$ and $g \in G$ we define the partial automorphism act $[g, X]: X \rightarrow_{p} X$ by conjugation: act $[g, X](y)=z$ if and only if $y, z \in X$ and $g^{-1} y g=z$. For a reduced $t$-sequence $u$, act $[u, X]$ is defined as act $[g, X]$, where $g$ is the element of $G$ represented by $u$. The goal of this section is to prove the following lemma:

Lemma 3.4. There exists a subgroup $X \leq A \cap B$ and for all $\alpha, \beta \in\{1,-1\}$ there exist $s_{\alpha \beta} \in \operatorname{Red}(H, t)$ such that

- $s_{\alpha \beta} \in t^{\alpha} \cdot \operatorname{Red}(H, t) \cdot t^{\beta}$,
- $X$ is a normal subgroup of $G$, i.e., for all $g \in G$ : act $[g, X]$ is an (totally defined) automorphism of $X$, and
- for all $c, d \in A \cup B$, if $c s_{\alpha \beta}=s_{\alpha \beta} d$ in $G$ then $c=d \in X$.

The subgroup $X$ and the reduced $t$-sequences $s_{\alpha \beta}$ will be used in Section 3.4 in order to construct reduced $t$-sequences with some desired behavior. The sequence $s_{\alpha \beta}$ has a stabilizing behaviour in the following sense: Note that for all $c, d \in A \cup B, c s_{\alpha \beta}$ and $s_{\alpha \beta} d$ are reduced $t$-sequences. If we have a diagram of the form

then we must have $c=d \in X$ by the last point from Lemma 3.4.
We will construct the subgroup $X$ as the limit of a decreasing chain $A \cap B \supseteq$ $X_{0} \supsetneq X_{1} \supsetneq X_{2} \cdots$. Since $A \cap B$ is finite, this chain has to terminate with some $X_{i}=X$.

Recall that $\varphi: A \rightarrow B$ is an isomorphism. We start with the subgroup

$$
Y=\left\{x \in A \cap B \mid \forall k \geq 0: \varphi^{k}(x) \in A \cap B\right\} \leq A \cap B
$$

Note that $Y$ is closed under $\varphi$. Since $\varphi$ is injective and $Y$ is finite, $\varphi \upharpoonright_{Y}$ is a permutation on the finite set $Y$. In particular, $Y$ is also closed under $\varphi^{-1}$. Let us fix a number $n \in \mathbb{N}$ such that $n-1>|A \cap B|$ and $\left(\varphi \upharpoonright_{Y}\right)^{n}=\operatorname{id}_{Y}$.

Lemma 3.5. For all $c, d \in A \cup B$, if $c t^{n}=t^{n} d$ in $G$ then $c=d \in Y$.
Proof. Assume that $c t^{n}=t^{n} d$ in $G$ for some $c, d \in A \cup B$. Since $c t^{n}$ and $t^{n} d$ are reduced $t$-sequences, we obtain a Van Kampen diagram of the following kind:

We get $c_{0}=c \in A, c_{n}=d \in B, c_{1}, \ldots, c_{n-1} \in A \cap B$, and $\varphi\left(c_{i}\right)=c_{i+1}$ for $0 \leq i<n$. Since $n-1>|A \cap B|$, there are $1 \leq i<j<n$ such that $c_{i}=c_{j}$. Thus, $\varphi$ enters a cycle at $c_{i} \in A \cap B$, i.e., $c_{i} \in Y$. Since $Y$ is closed under $\varphi$ and $\varphi^{-1}$, we get $c, c_{1}, \ldots, c_{n-1}, d \in Y$. Moreover, $\left(\varphi \upharpoonright_{Y}\right)^{n}=\operatorname{id}_{Y}$ implies that $c=d$.

Next we define sequences $s[\alpha, \beta]_{i} \in \operatorname{Red}(H, t)(\alpha, \beta \in\{1,-1\})$ and a subgroup $X_{i} \leq Y$ for all $i \geq 0$ inductively. We start with $i=0$ : Choose an element

$$
\begin{equation*}
h \in H \backslash(A \cup B), \tag{5}
\end{equation*}
$$

which will be fixed for the rest of Section $3 .{ }^{1}$ Let act $:=\operatorname{act}[h, Y]: Y \rightarrow_{p} Y$ and let

$$
X_{0}=\left\{x \in Y \mid \forall k \geq 0: \operatorname{act}^{k}(x) \text { is defined }\right\} \leq Y .
$$

Thus, act $\sum_{X_{0}}$ is a permutation on the finite subgroup $X_{0}$. Now choose a number $m \in \mathbb{N}$ such that $m+1>|Y|$ and $\left(\left.\operatorname{act}\right|_{X_{0}}\right)^{m}=\operatorname{id}_{X_{0}}$, and define $(n>0$ is the constant from Lemma 3.5):

$$
\begin{aligned}
s[1,1]_{0} & =\left(t^{n} h\right)^{m} t^{n} \\
s[1,-1]_{0} & =\left(t^{n} h\right)^{m} t^{-n} \\
s[-1,1]_{0} & =\left(t^{-n} h\right)^{m} t^{n} \\
s[-1,-1]_{0} & =\left(t^{-n} h\right)^{m} t^{-n}
\end{aligned}
$$

Note that $s[\alpha, \beta]_{0}$ is a reduced $t$-sequence (because $h \notin A \cup B$ ) and $s[\alpha, \beta]_{0} \in$ $t^{\alpha} \cdot \operatorname{Red}(H, t) \cdot t^{\beta}$.

Lemma 3.6. For all $c, d \in A \cup B$, if cs $[\alpha, \beta]_{0}=s[\alpha, \beta]_{0} d$ in $G$, then $c=d \in X_{0}$.
Proof. We restrict to the case that $\alpha=\beta=1$, the other cases can be dealt analogously. Assume that we have $c, d \in A \cup B$ with $c\left(t^{n} h\right)^{m} t^{n}=\left(t^{n} h\right)^{m} t^{n} d$. Due to Lemma 3.5 we obtain a diagram of the following form, where $c_{0}, c_{1}, \ldots, c_{m} \in Y$ :

[^0]Hence, $\operatorname{act}\left(c_{i}\right)=c_{i+1}$ for $0 \leq i<m$. Since $m+1>|Y|$, there are $i<j$ with $c_{i}=c_{j}$. Thus, act enters a cycle at $c_{i}$, i.e., $c_{i} \in X_{0}$. But since $X_{0}$ is closed under act and act ${ }^{-1}$, we get $c, c_{1}, \ldots, c_{m-1}, d \in X_{0}$. Moreover, $\left(\left.\operatorname{act}\right|_{X_{0}}\right)^{m}=\operatorname{id}_{X_{0}}$ implies $c=d$.

Now assume that for some $i \geq 0$, reduced $t$-sequences $s[\alpha, \beta]_{i} \in \operatorname{Red}(H, t)$ and a subgroup $X_{i} \leq A \cap B$ with the following properties are already defined:

- $s[\alpha, \beta]_{i} \in t^{\alpha} \cdot \operatorname{Red}(H, t) \cdot t^{\beta}$
- for all $c, d \in A \cup B$, if $c s[\alpha, \beta]_{i}=s[\alpha, \beta]_{i} d$ in $G$ then $c=d \in X_{i}$

If for all $g \in G$, act $\left[g, X_{i}\right]$ is totally defined, i.e., $X_{i}$ is a normal subgroup of $G$, then we stop and set $s_{\alpha \beta}=s[\alpha, \beta]_{i}$ and $X=X_{i}$, which proves Lemma 3.4. Otherwise there exists $g \in G$ such that act $=\operatorname{act}\left[g, X_{i}\right]$ is not totally defined on $X_{i}$. We identify $g$ with a reduced $t$-sequence representing $g$. Define

$$
X_{i+1}=\left\{x \in X_{i} \mid \forall k \geq 0: \operatorname{act}^{k}(x) \text { is defined }\right\}<X_{i} .
$$

Note that there exist $\alpha, \beta \in\{1,-1\}$ such that $t^{\alpha} \cdot g \cdot t^{\beta}$ is again a reduced $t$-sequence. Let us assume that $\alpha=\beta=1$, the other cases can be dealt analogously.

Clearly, act $\prod_{X_{i+1}}$ is a permutation on the subgroup $X_{i+1}$. Let $m$ be such that $m+1>\left|X_{i}\right|$ and $\left(\left.\operatorname{act}\right|_{X_{i+1}}\right)^{m}=\operatorname{id}_{X_{i+1}}$, and define:

$$
\begin{aligned}
s[1,1]_{i+1} & =\left(s[1,1]_{i} g\right)^{m} s[1,1]_{i} \\
s[1,-1]_{i+1} & =\left(s[1,1]_{i} g\right)^{m} s[1,-1]_{i} \\
s[-1,1]_{i+1} & =s[-1,1]_{i}\left(g s[1,1]_{i}\right)^{m} \\
s[-1,-1]_{i+1} & =s[-1,1]_{i}\left(g s[1,1]_{i}\right)^{m-1} g s[1,-1]_{i}
\end{aligned}
$$

By construction we have $s[\alpha, \beta]_{i+1} \in t^{\alpha} \cdot \operatorname{Red}(H, t) \cdot t^{\beta}$. The following lemma can be proved analogously to Lemma 3.6:

Lemma 3.7. For all $c, d \in A \cup B$, if $c s[\alpha, \beta]_{i+1}=s[\alpha, \beta]_{i+1} d$ in $G$, then $c=d \in X_{i+1}$.

This concludes the proof of Lemma 3.4.

### 3.3 Reducing to the existential positive theory

Our strategy for reducing the positive theory of the HNN-extension $G$ to the existential positive theory of $G$ with rational constraints is similar to [17, 19]: Given a positive sentence $\theta$, which is interpreted over $G$, we construct an existential positive sentence $\theta^{\prime}$ with subgroup constraints of a very restricted form, which is interpreted over a multiple HNN-extension $\mathbb{G}$ of $G$, where only finite subgroups of $H \leq G$ are associated (in fact, $X \subseteq A \cap B$ from Lemma 3.4 will be associated with itself). Roughly speaking, $\theta^{\prime}$ results from $\theta$ by replacing the universally quantified variables by the stable letters of the HNN-extension $\mathbb{G}$.

Let $X \leq A \cap B$ be the subgroup from Lemma 3.4. Recall that with $\operatorname{In}(X, G)$ we denote the group of all automorphisms $f$ of $X$ such that for some $g \in G$ we have: $f(c)=g^{-1} c g$ for all $c \in X$. In the following, we use the abbreviation

$$
\operatorname{In}=\operatorname{In}(X, G)
$$

For new constants $k_{1}, \ldots, k_{m} \notin G$ and $f_{1}, \ldots, f_{m} \in$ In we define the HNNextension

$$
G_{k_{1}, \ldots, k_{m}}^{f_{1}, \ldots, f_{m}}=\left\langle G, k_{1}, \ldots, k_{j} ; k_{i}^{-1} c k_{i}=f_{i}(c)(c \in X, 1 \leq i \leq m)\right\rangle .
$$

The next two lemmas yield the main steps for the reduction from the positive to the existential positive theory. For the further consideration let us fix $m \in \mathbb{N}$, groups $H_{1}, \ldots, H_{m}, H^{\prime}$ such that $H \subseteq H_{i} \subseteq H^{\prime}$ for $1 \leq i \leq m$. Let

$$
\begin{aligned}
G_{i} & =\left\langle H_{i}, t ; t^{-1} a t=\varphi(a)(a \in A)\right\rangle \\
G^{\prime} & =\left\langle H^{\prime}, t ; t^{-1} a t=\varphi(a)(a \in A)\right\rangle
\end{aligned}
$$

These groups contain $G=\left\langle H, t ; t^{-1} a t=\varphi(a)(a \in A)\right\rangle$. Let $k \notin G^{\prime}$ be a new constant and let $f \in \operatorname{In}$. In the following symbols with a tilde like $\widetilde{x}$ will denote sequences of arbitrary length over some set that will be always clear form the context. If say $\widetilde{a}=\left(a_{1}, \ldots, a_{m}\right)$, then $\widetilde{a} \in A$ means $a_{1} \in A, \ldots, a_{m} \in A$.

Lemma 3.8. Assume that $\phi\left(x, y_{1}, \ldots, y_{m}, \widetilde{z}\right)$ is a positive boolean formula with constants over the group $G$. If

$$
\exists y_{1} \cdots \exists y_{m}\left\{\begin{array}{l}
\bigwedge_{1 \leq i \leq m} y_{i} \in\left(G_{i}\right)_{k}^{f} \wedge \\
\phi\left(k, y_{1}, \ldots, y_{m}, \widetilde{u}\right)
\end{array}\right\} \text { in }\left(G^{\prime}\right)_{k}^{f}
$$

then

$$
\forall x \in\{g \in G \mid \operatorname{act}[g, X]=f\} \exists y_{1} \cdots \exists y_{m}\left\{\bigwedge_{1 \leq i \leq m} y_{i} \in G_{i} \wedge,\right.
$$

Proof. Assume that there are $g_{i} \in\left(G_{i}\right)_{k}^{f}(1 \leq i \leq m)$ such that $\phi\left(k, g_{1}, \ldots, g_{m}, \widetilde{u}\right)$ is true in $\left(G^{\prime}\right)_{k}^{f}$. Let $g \in G$ be an arbitrary element with act $[g, X]=f$. Then we can define a homomorphism $\rho:\left(G^{\prime}\right)_{k}^{f} \rightarrow G^{\prime}$ by $\rho(k)=g$ and $\rho(g)=g$ for $g \in G^{\prime}$. This homomorphism is well-defined since act $[k, X]=\operatorname{act}[g, X]$. Then $\rho\left(g_{i}\right) \in G_{i}$ for $1 \leq i \leq m$ and, since $\phi$ is a positive formula, $\phi\left(g, \rho\left(g_{1}\right), \ldots, \rho\left(g_{m}\right), \tilde{u}\right)$ is true in $G^{\prime}$. This proves the lemma.

Note that the assertion of Lemma 3.8 does not hold in general, if $\phi$ involves negations. For example $\forall x: x \neq 1$ is false, but $k \neq 1$ is true. On the other hand, the converse implication of Lemma 3.8 is true for arbitrary formulas:

Lemma 3.9. Assume that $\phi\left(x, y_{1}, \ldots, y_{m}, \widetilde{z}\right)$ is a (not necessarily positive) boolean formula with constants over the group $G$. If

$$
\forall x \in\{g \in G \mid \operatorname{act}[g, X]=f\} \exists y_{1} \cdots \exists y_{m}\left\{\begin{array}{c}
\bigwedge_{1 \leq i \leq m} y_{i} \in G_{i} \wedge \\
\phi\left(x, y_{1}, \ldots, y_{m}, \widetilde{u}\right)
\end{array}\right\} \text { in } G^{\prime}
$$

then

$$
\exists y_{1} \cdots \exists y_{m}\left\{\begin{array}{l}
\bigwedge_{1 \leq i \leq m} y_{i} \in\left(G_{i}\right)_{k}^{f} \wedge \\
\phi\left(k, y_{1}, \ldots, y_{m}, \widetilde{u}\right)
\end{array}\right\} \text { in }\left(G^{\prime}\right)_{k}^{f}
$$

Let us postpone the quite involved proof of Lemma 3.9. The following theorem yields the reduction from the positive to the existential theory.

Theorem 3.10. Let $\theta(\widetilde{z}) \equiv \forall x_{1} \exists y_{1} \cdots \forall x_{n} \exists y_{n} \phi\left(x_{1}, \ldots, x_{n}, y_{1}, \ldots, y_{n}, \widetilde{z}\right)$ where $\phi$ a positive boolean combination of word equations (with constants) over the group $G$. For all $\widetilde{u} \in G$ we have $\theta(\widetilde{u})$ in $G$ if and only if

$$
\bigwedge_{f_{1} \in \operatorname{In}} \exists y_{1} \cdots \bigwedge_{f_{n} \in \operatorname{In}} \exists y_{n}\left\{\begin{array}{l}
\bigwedge_{1 \leq i \leq n} y_{i} \in G_{k_{1}, \ldots, k_{i}}^{f_{1}, \ldots, f_{i}} \wedge  \tag{6}\\
\phi\left(k_{1}, \ldots, k_{n}, y_{1}, \ldots, y_{n}, \widetilde{u}\right) \text { in } G_{k_{1}, \ldots, k_{n}}^{f_{1}, \ldots, f_{n}}
\end{array}\right\}
$$

Proof. The proof is similar to the proof of [6, Theorem 17]. We proceed by induction on $n$. The case $n=0$ is clear. If $n>0$, then inductively we can assume that for all $s_{1}, t_{1}, \widetilde{u} \in G$ we have

$$
\forall x_{2} \exists y_{2} \cdots \forall x_{n} \exists y_{n} \phi\left(s_{1}, x_{2}, \ldots, x_{n}, t_{1}, y_{2}, \ldots, y_{n}, \widetilde{u}\right) \text { in } G
$$

if and only if

$$
\bigwedge_{f_{2} \in \operatorname{In}} \exists y_{2} \cdots \bigwedge_{f_{n} \in \operatorname{In}} \exists y_{n}\left\{\begin{array}{l}
\bigwedge_{2 \leq i \leq n} y_{i} \in G_{k_{2}, \ldots, k_{i}}^{f_{2}, \ldots, f_{i}} \wedge \\
\phi\left(s_{1}, k_{2}, \ldots, k_{n}, t_{1}, y_{2}, \ldots, y_{n}, \widetilde{u}\right) \text { in } G_{k_{2}, \ldots, k_{n}}^{f_{2}, \ldots, f_{n}}
\end{array}\right\}
$$

Thus, for all $\widetilde{u} \in G$ we have

$$
\forall x_{1} \exists y_{1} \cdots \forall x_{n} \exists y_{n} \phi\left(x_{1}, \ldots, x_{n}, y_{1}, \ldots, y_{n}, \widetilde{u}\right) \text { in } G
$$

if and only if
$\forall x_{1} \in G \exists y_{1} \bigwedge_{f_{2} \in \operatorname{In}} \exists y_{2} \cdots \bigwedge_{f_{n} \in \operatorname{In}} \exists y_{n}\left\{\begin{array}{l}\bigwedge_{1 \leq i \leq n} y_{i} \in G_{k_{2}, \ldots, k_{i}}^{f_{2}, \ldots, f_{i}} \wedge \\ \phi\left(x_{1}, k_{2}, \ldots, k_{n}, y_{1}, \ldots, y_{n}, \widetilde{u}\right) \text { in } G_{k_{2}, \ldots, k_{n}}^{f_{2}, \ldots, f_{n}}\end{array}\right\}$.
Now we replace the universal quantifier $\forall x_{1} \in G$ by $\bigwedge_{f_{1} \in \text { In }} \forall x_{1} \in\{g \in G \mid$ $\left.\operatorname{act}[g, X]=f_{1}\right\}$. Hence, by Lemmas 3.8 and 3.9 the above formula is true in
$G_{k_{2}, \ldots, k_{n}}^{f_{2}, \ldots, f_{n}}$ if and only if

$$
\bigwedge_{f_{1} \in \operatorname{In}} \exists y_{1} \bigwedge_{f_{2} \in \operatorname{In}} \exists y_{2} \cdots \bigwedge_{f_{n} \in \operatorname{In}} \exists y_{n}\left\{\begin{array}{l}
\bigwedge_{1 \leq i \leq n} y_{i} \in G_{k_{1}, \ldots, k_{i}}^{f_{1}, \ldots, f_{i}} \wedge \\
\phi\left(k_{1}, k_{2}, \ldots, k_{n}, y_{1}, \ldots, y_{n}, \widetilde{u}\right) \text { in } G_{k_{1}, \ldots, k_{n}}^{f_{1}, \ldots, f_{n}}
\end{array}\right\}
$$

Remark 3.11. In [5], a result analogous to Theorem 3.10 for the case that $G$ is a free product (in fact, a certain graph product) was shown. In this case, the new generators $k_{1}, \ldots, k_{n}$ do not interact with the group $G$, i.e., the HNN-extension $G_{k_{1}, \ldots, k_{n}}^{f_{1}, \ldots, f_{n}}$ is replaced by the free product $G * F\left(k_{1}, \ldots, k_{n}\right)$, where $F\left(k_{1}, \ldots, k_{n}\right)$ is the free group generated by $k_{1}, \ldots, k_{n}$. For the more general case that $G$ is an HNN-extension, we cannot avoid some nontrivial interaction between $k_{i}$ and $G_{i}$ : this interaction is expressed by the identities $k_{i}^{-1} c k_{i}=f_{i}(c)$ for $c \in X$ in the HNN-extension $G_{k_{1}, \ldots, k_{n}}^{f_{1}, \ldots, f_{n}}$. In order to use Theorem 2.1, it is crucial that the group $X$ is finite.

Note that the sentence in (6) is not interpreted in a single HNN-extension of $G$. In order to reduce (6) to an existential statement over a single group $\mathbb{G}$, assume that $\operatorname{In}=\left\{\rho_{1}, \ldots, \rho_{\ell}\right\}$. Let $S=\{1, \ldots, \ell\}$. For $\alpha>0$ let $S \leq \alpha$ be the set of all non-empty words over $S$ of length at most $\alpha$. For $\tau \in S^{n}$ and $1 \leq \alpha \leq n$ let $\tau \upharpoonright \alpha \in S^{\alpha}$ be the prefix of $\tau$ of length $\alpha$, whereas $\tau[\alpha] \in\{1, \ldots, \ell\}$ denotes the symbol at position $\alpha$ in $\tau$. Take new constants $k_{\sigma}$ for every $\sigma \in S \leq n$ and define the multiple HNN-extension $\mathbb{G}$ over $G$ that results by adding to $G$ for every word $\sigma \in S \leq n$ the stable letters $k_{\sigma}$ together with the defining equation $k_{\sigma}^{-1} c k_{\sigma}=\rho_{i}(c)(c \in X)$, when $i$ is the last symbol of the word $\sigma$. This is a fixed multiple HNN-extension over $G$, where only finite subgroups are associated.
Lemma 3.12. For all $\tilde{u} \in G$, we have

$$
\bigwedge_{f_{1} \in \operatorname{In}} \exists y_{1} \cdots \bigwedge_{f_{n} \in \operatorname{In}} \exists y_{n}\left\{\begin{array}{l}
\bigwedge_{1 \leq i \leq n} y_{i} \in G_{k_{1}, \ldots, k_{i}}^{f_{1}, \ldots, f_{i}} \wedge  \tag{7}\\
\phi\left(k_{1}, \ldots, k_{n}, y_{1}, \ldots, y_{n}, \widetilde{u}\right) \text { in } G_{k_{1}, \ldots, k_{n}}^{f_{1}, \ldots, f_{n}}
\end{array}\right\}
$$

if and only if

$$
\left(\exists y_{\sigma}\right)_{\sigma \in S \leq n} \bigwedge_{\tau \in S^{n}}\left\{\begin{array}{l}
\bigwedge_{\alpha=1}^{n} y_{\tau \upharpoonright \alpha} \in G_{k_{\tau \upharpoonright 1}, \ldots, k_{\tau \upharpoonright \alpha}}^{\rho_{\tau[1]}, \ldots, \rho_{\tau[\alpha]}} \wedge  \tag{8}\\
\phi\left(k_{\tau \upharpoonright 1}, \ldots, k_{\tau \upharpoonright n}, y_{\tau \upharpoonright 1}, \ldots, y_{\tau \upharpoonright n}, \tilde{u}\right)
\end{array}\right\} i n \mathbb{G}
$$

Proof. By tranforming sentence (7) into prenex normal form, we obtain the equivalent sentence

$$
\left(\exists y_{\sigma}\right)_{\sigma \in S \leq n} \bigwedge_{\tau \in S^{n}}\left\{\begin{array}{l}
\bigwedge_{\alpha=1}^{n} y_{\tau \upharpoonright \alpha} \in G_{k_{1}, \ldots, k_{\alpha}}^{\rho_{\tau[1]}, \ldots, \rho_{\tau[\alpha]}} \wedge  \tag{9}\\
\phi\left(k_{1}, \ldots, k_{n}, y_{\tau\lceil 1}, \ldots, y_{\tau \upharpoonright n}, \tilde{u}\right) \text { in } G_{k_{1}, \ldots, k_{n}}^{\rho_{\tau[1]}, \ldots, \rho_{\tau[n]}}
\end{array}\right\}
$$

It remains to show that $(8) \Leftrightarrow(9)$. First assume that (9) holds. For every $\tau \in S^{n}$ we define an isomorphism

$$
h_{\tau}: G_{k_{1}, \ldots, k_{n}}^{\rho_{\tau[1]}, \ldots, \rho_{\tau[n]}} \rightarrow G_{k_{\tau \mid 1}, \ldots, k_{\tau \mid n}}^{\rho_{\tau[1]}, \ldots, \rho_{\tau[n]}}
$$

by $h_{\tau}(g)=g$ for $g \in G$ and $h_{\tau}\left(k_{i}\right)=k_{\tau \uparrow i}$ for $1 \leq i \leq n$. Since $G_{k_{\tau} \mid 1, \ldots, k_{\tau \uparrow n}}^{\rho_{\tau[1]}, \ldots, \rho_{\tau[n]}} \subseteq \mathbb{G}$, we can view $h_{\tau}$ as an embedding of $G_{k_{1}, \ldots, k_{n}}^{\rho_{\tau[1]}, \ldots, \rho_{\tau[n]}}$ into $\mathbb{G}$. Since (9) is true, there exist $y_{\sigma}\left(\sigma \in S^{\leq n}\right)$ such that for every $\tau \in S^{n}$ we have:

- $y_{\tau \upharpoonright \alpha} \in G_{k_{1}, \ldots, k_{\alpha}}^{\rho_{\tau[1]}, \ldots, \rho_{\tau[\alpha]}}$ for $1 \leq \alpha \leq n$
- $\phi\left(k_{1}, \ldots, k_{n}, y_{\tau \uparrow 1}, \ldots, y_{\tau \uparrow n}, \tilde{u}\right)$ in the group $G_{k_{1}, \ldots, k_{n}}^{\rho_{\tau[1]}, \ldots, \rho_{\tau[n]}}$

By applying for every $\tau \in S^{n}$ the embedding $h_{\tau}$, we obtain $y_{\sigma}\left(\sigma \in S^{\leq n}\right)$ such that for every $\tau \in S^{n}$ we have:

- $y_{\tau \upharpoonright \alpha} \in G_{k_{\tau\lceil 1}, \ldots, k_{\tau \uparrow \alpha}}^{\rho_{\tau[1]}, \ldots, \rho_{\tau[\alpha]}}$ for $1 \leq \alpha \leq n$
- $\phi\left(k_{\tau \upharpoonright 1}, \ldots, k_{\tau \upharpoonright n}, y_{\tau \upharpoonright 1}, \ldots, y_{\tau \upharpoonright n}, \tilde{u}\right)$ in the group $\mathbb{G}$

Hence, (8) is true.
Now assume that (8) is true. Then, for every $\tau \in S^{n}$ we define the isomorphism

$$
h_{\tau}: G_{k_{\tau \uparrow 1}, \ldots, k_{\tau\lceil n}}^{\rho_{\tau[1]}, \ldots, \rho_{\tau[n]}} \rightarrow G_{k_{1}, \ldots, k_{n}}^{\rho_{\tau[1]}, \ldots, \rho_{\tau[n]}}
$$

by $h_{\tau}(g)=g$ for $g \in G$ and $h_{\tau}\left(k_{\tau \upharpoonright i}\right)=k_{i}$ for $1 \leq i \leq n$. Since (8) is true there are $y_{\sigma}\left(\sigma \in S^{\leq n}\right)$ such that for every $\tau \in S^{n}$ :

- $y_{\tau \upharpoonright \alpha} \in G_{k_{\tau \mid 1}, \ldots, k_{\tau \upharpoonright \alpha}}^{\rho_{\tau[1]}, \ldots, \rho_{\tau[\alpha]}}$ for $1 \leq \alpha \leq n$
- $\phi\left(k_{\tau \upharpoonright 1}, \ldots, k_{\tau \uparrow n}, y_{\tau \uparrow 1}, \ldots, y_{\tau \uparrow n}, \tilde{u}\right)$ is true in the group $\mathbb{G}$ and hence is also true in $G_{k_{\tau[1}, \ldots, k_{\tau \uparrow n}}^{\rho_{\tau[1]}, \ldots, \rho_{\tau[n]}} \subseteq \mathbb{G}$

By applying the isomorphisms $h_{\tau}$ we obtain $y_{\sigma}\left(\sigma \in S^{\leq n}\right)$ such that for every $\tau \in S^{n}$ we have:

- $y_{\tau \upharpoonright \alpha} \in G_{k_{1}, \ldots, k_{\alpha}}^{\rho_{\tau[1]}, \ldots, \rho_{\tau[\alpha]}}$ for $1 \leq \alpha \leq n$
- $\phi\left(k_{1}, \ldots, k_{n}, y_{\tau \upharpoonright 1}, \ldots, y_{\tau \uparrow n}, \tilde{u}\right)$ in the group $G_{k_{1}, \ldots, k_{n}}^{\rho_{\tau[1]}, \ldots, \rho_{\tau[n]}}$

Thus, (9) is true.
To complete the proof of Theorem 3.1, notice that an iterated application of Theorem 2.1 enables us to reduce the existential theory of $\mathbb{G}$ with constraints of the form $G_{k_{\tau\lceil 1}, \ldots, k_{\tau\lceil\alpha}}^{\rho_{\tau[1]}, \ldots, \rho_{\tau}}$ to the existential theory of $G$.

It remains to prove Lemma 3.9, which will be down by a reduction to reduced $t$-sequences. For this, we need one more lemma concerning reduced $t$-sequences. Note that elements from $G^{\prime}$ (resp. $G_{i}$ ) can be represented by reduced $t$-sequences from $\operatorname{Red}\left(H^{\prime}, t\right)$ (resp. $\left.\operatorname{Red}\left(H_{i}, t\right)\right)$. Fix a tuple

$$
\begin{equation*}
\widetilde{w}=\left(w_{1}, \ldots, w_{N}\right) \tag{10}
\end{equation*}
$$

where $w_{i} \in \operatorname{Red}(H, t)$ is a reduced $t$-sequence which represents the fixed group element $u_{i} \in G$. Recall from Section 3.1 that we view $\operatorname{Red}(F, t)$ (where $F$ is some base group) as a relational structure equipped with the multiplication in the base group $F$, and the concatenation and inversion of reduced $t$-sequences.

Lemma 3.13. Let $\chi\left(x, y_{1}, \ldots, y_{m}, \widetilde{z}\right)$ be a (not necessarily positive) boolean formula over the signature of the structure $\operatorname{Red}\left(H^{\prime}, t\right)$ and with constants from $\operatorname{Red}(H, t)$. If

$$
\forall x \in\{u \in \operatorname{Red}(H, t) \mid \operatorname{act}[u, X]=f\} \exists y_{1} \cdots \exists y_{m}\left\{\begin{array}{l}
\bigwedge_{1 \leq i \leq m} y_{i} \in \operatorname{Red}\left(H_{i}, t\right) \\
\wedge \chi\left(x, y_{1}, \ldots, y_{m}, \widetilde{w}\right)
\end{array}\right\}
$$

in $\operatorname{Red}\left(H^{\prime}, t\right)$, then there are $v_{1}, v_{2} \in \operatorname{Red}(H, t)$ with act $\left[v_{1}, X\right] \circ f \circ$ act $\left[v_{2}, X\right]=f$ and

$$
\exists y_{1} \cdots \exists y_{m}\left\{\begin{array}{l}
\bigwedge_{1 \leq i \leq m} y_{i} \in \operatorname{Red}\left(\left(H_{i}\right)_{k}^{f}, t\right) \\
\wedge \chi\left(v_{1} \cdot k \cdot v_{2}, y_{1}, \ldots, y_{m}, \widetilde{w}\right)
\end{array}\right\} \quad \text { in } \operatorname{Red}\left(\left(H^{\prime}\right)_{k}^{f}, t\right)
$$

The proof of Lemma 3.13 is the main technical difficulty and shifted to the next section.

Using Lemma 3.13, we can finish the proof of Lemma 3.9: Assume that

$$
\forall x \in\{g \in G \mid \operatorname{act}[g, X]=f\} \exists y_{1} \cdots \exists y_{m}\left\{\begin{array}{l}
\bigwedge_{1 \leq i \leq m} y_{i} \in G_{i} \wedge \\
\phi\left(x, y_{1}, \ldots, y_{m}, \widetilde{u}\right)
\end{array}\right\} \text { in } G^{\prime}
$$

By Lemma 3.3, we obtain a boolean formula $\chi$ over the structure $\operatorname{Red}\left(H^{\prime}, t\right)$ such that
$\forall x \in\{u \in \operatorname{Red}(H, t) \mid \operatorname{act}[u, X]=f\} \exists y_{1} \cdots \exists y_{m} \exists \widetilde{y}\left\{\begin{array}{l}\bigwedge_{1 \leq i \leq m} y_{i} \in \operatorname{Red}\left(H_{i}, t\right) \\ \wedge \widetilde{y} \in \operatorname{Red}\left(H^{\prime}, t\right) \wedge \\ \chi\left(x, y_{1}, \ldots, y_{m}, \widetilde{y}, \widetilde{w}\right)\end{array}\right\}$
is true in $\operatorname{Red}\left(H^{\prime}, t\right)$. Note that by applying Lemma 3.3, we only introduce a sequence $\widetilde{y}$ of new existentially quantified variables. Thus, by Lemma 3.13 there exist $v_{1}, v_{2} \in \operatorname{Red}(H, t)$ such that $\operatorname{act}\left[v_{1}, X\right] \circ f \circ \operatorname{act}\left[v_{2}, X\right]=f$ and

$$
\exists y_{1} \cdots \exists y_{m} \exists \widetilde{y}\left\{\begin{array}{l}
\bigwedge_{1 \leq i \leq m} y_{i} \in \operatorname{Red}\left(\left(H_{i}\right)_{k}^{f}, t\right) \\
\wedge \widetilde{y} \in \operatorname{Red}\left(\left(H^{\prime}\right)_{k}^{f}, t\right) \\
\wedge \chi\left(v_{1} \cdot k \cdot v_{2}, y_{1}, \ldots, y_{m}, \widetilde{y}, \widetilde{w}\right)
\end{array}\right\} \quad \text { in } \operatorname{Red}\left(\left(H^{\prime}\right)_{k}^{f}, t\right)
$$

By applying Lemma 3.3 again (with $G$ replaced by $\left(G^{\prime}\right)_{k}^{f}$ ), it follows that

$$
\begin{equation*}
\exists y_{1} \cdots \exists y_{m}\left\{\bigwedge_{1 \leq i \leq m} y_{i} \in\left(G_{i}\right)_{k}^{f} \wedge \phi\left(v_{1} k v_{2}, y_{1}, \ldots, y_{m}, \widetilde{u}\right)\right\} \text { in }\left(G^{\prime}\right)_{k}^{f} \tag{11}
\end{equation*}
$$

where $v_{i} \in \operatorname{Red}(H, t)$ is identified with the group element from $G$ it represents. Note that $\operatorname{act}\left[v_{1}^{-1} k v_{2}^{-1}, X\right]=\operatorname{act}\left[v_{1}, X\right]^{-1} \circ f \circ \operatorname{act}\left[v_{2}, X\right]^{-1}=f=\operatorname{act}[k, X]$. Thus, we can define a group homomorphism $h:\left(G^{\prime}\right)_{k}^{f} \rightarrow\left(G^{\prime}\right)_{k}^{f}$ by $h(k)=$ $v_{1}^{-1} k v_{2}^{-1}$ and $h(x)=x$ for $x \in G^{\prime}$. First, note that $h$ is injective (the homomorphism defined by $g(k)=v_{1} k v_{2}$ defines an inverse). Hence, since constants from $G^{\prime}$ are mapped to itself by $h$, the truth value of all (negated) equations in (11) is preserved by $h$. Moreover, $h\left(v_{1} k v_{2}\right)=v_{1} v_{1}^{-1} k v_{2}^{-1} v_{2}=k$ in $\left(G^{\prime}\right)_{k}^{f}$. Hence, applying $h$ to the above statement yields

$$
\exists y_{1} \cdots \exists y_{m}\left\{\bigwedge_{1 \leq i \leq m} y_{i} \in\left(G_{i}\right)_{k}^{f} \wedge \phi\left(k, y_{1}, \ldots, y_{m}, \widetilde{u}\right)\right\} \text { in }\left(G^{\prime}\right)_{k}^{f}
$$

### 3.4 Proof of Lemma 3.13

The following data were already fixed:

- the element $h \in H \backslash(A \cup B)$ from (5) in Section 3.2
- the finite normal subgroup $X \leq A \cap B$ and the elements $s_{\alpha \beta} \in \operatorname{Red}(H, t)$ ( $\alpha, \beta \in\{1,-1\}$ ) from Lemma 3.4
- $f \in \operatorname{In}$ from Section 3.3
- the sets $\operatorname{Red}(H, t) \subseteq \operatorname{Red}\left(H_{i}, t\right) \subseteq \operatorname{Red}\left(H^{\prime}, t\right) \subseteq \operatorname{Red}\left(\left(H^{\prime}\right)_{k}^{f}, t\right)$ of reduced $t$-sequences
- the tuple $\widetilde{w}=\left(w_{1}, \ldots, w_{N}\right)$ with $w_{i} \in \operatorname{Red}(H, t)$ from (10) in Section 3.3

Moreover, let us fix a (not necessarily positive) boolean formula $\chi\left(x, y_{1}, \ldots, y_{m}, \widetilde{z}\right)$ over the signature of the structure $\operatorname{Red}\left(H^{\prime}, t\right)$. Thus, $\chi$ is a boolean combination of propositions of the form $x \cdot y \sim z, x \sim y^{-1}$, and $x y=z$ in the base group $H^{\prime}$, where $x, y$, and $z$ are either variables or constants from $\operatorname{Red}\left(H^{\prime}, t\right)$. Let $W$ be the union of $\left\{w_{1}, \ldots, w_{N}\right\}$ and the set of all constants appearing in $\chi$, and let $d$ be the number of atomic propositions of the form $x \cdot y \sim z$ that occur in $\chi$. Choose a number $\lambda>2 d$ such that $|X|$ ! divides $\lambda-1$. Finally, choose an element $x_{f} \in \operatorname{Red}(H, t)$ such that act $\left[x_{f}, X\right]=f$, which exists since $f \in \operatorname{In}$. By appending suitable sequences $s_{\alpha \beta}$ to the left and right of $x_{f}$, we can enforce that $x_{f}$ is of the form $t \cdot y \cdot t$ for some $y \in \operatorname{Red}(H, t)$.

A $t$-system of degree $n(n \geq 2)$ is a tuple $\mathcal{R}=\left(r_{0}, \ldots, r_{\lambda}\right)$ with

$$
r_{i} \in(t h)^{|X|!}\left\{(t h)^{|X|!},\left(t^{-1} h\right)^{|X|!}\right\}^{n} t^{|X|!}
$$

The value of $n$ will be made more precise later; but recall that $\lambda$ is already defined. The idea is to encode sequences over a binary alphabet $\{a, b\}$ using the correspondence $a=(t h)^{|X|!}$ and $b=\left(t^{-1} h\right)^{|X|!}$. The information density of a sequence $r_{i}$ is only $\frac{n}{(n+1) 2|X|!+|X|!} \geq \frac{1}{5|X|!}$, but since $|X|$ ! is a constant, this won't be a problem. The exponent $|X|$ ! enforces that the sequences $r_{i}^{\alpha}$ $(\alpha \in\{1,-1\})$ have a trivial action by conjugation on the subgroup $X$. The element $h$ makes sequences reduced: since $h \in H \backslash(A \cup B), t^{-1} h t$ and $t h t^{-1}$ are reduced $t$-sequences. Finally, the initial (resp. final) sequence $(t h)^{|X|!}$ (resp. $t^{|X|!}$ ) ensures that every $r_{i}$ starts (resp. ends) with $t$. It follows that for every $1 \leq i \leq \lambda, r_{i-1} s_{11} x_{f} s_{11} r_{i}$ is a reduced $t$-sequence with act $\left[r_{i-1} s_{11} x_{f} s_{11} r_{i}, X\right]=$ $\operatorname{act}\left[x_{f}, X\right]=f$.

There are $2^{n(\lambda+1)} t$-systems of degree $n$. The $t$-system $\mathcal{R}=\left(r_{0}, \ldots, r_{\lambda}\right)$ has no long overlapping, if for all $0 \leq i, j \leq \lambda$ and $\alpha, \beta \in\{1,-1\}$ we have: ${ }^{2}$ if $\pi_{t}\left(r_{i}^{\alpha}\right)=x y$ and $\pi_{t}\left(r_{j}^{\beta}\right)=y z$, and $|y| \geq \frac{\left|r_{i}\right|-\left|s_{11} x_{f} s_{11}\right|}{2}$ then: $x=z=\varepsilon, i=j$, and $\alpha=\beta$.

This condition implies that if we have a Van Kampen diagram of the form shown in Section 3.1, the upper bow contains a segment $r_{i}^{\alpha}$, which overlapps a segment $r_{j}^{\beta}$ in the lower bow, then either these two segments are exactly opposite to each other (and $i=j$ and $\alpha=\beta$ ), or their overlapping region has length less than $\frac{\left|r_{i}\right|-\left|s_{11} x_{f} s_{11}\right|}{2}$.

The next lemma follows immediately from the above definition:
Lemma 3.14. Assume that $\mathcal{R}$ has no long overlapping. If

$$
\left(r_{i-1} s_{11} x_{f} s_{11} r_{i}\right)^{\alpha} \sim p \cdot r_{j}^{\beta} \cdot q
$$

for $p, q \in \operatorname{Red}(H, t)$ and $\alpha, \beta \in\{1,-1\}$, then we either have $|p|=0$ or $|q|=0$, i.e., $r_{j}^{\beta}$ cannot be properly contained in a segment which is opposite to a segment $\left(r_{i-1} s_{11} x_{f} s_{11} r_{i}\right)^{\alpha}$ in a diagram.

Lemma 3.15. There exists $n_{0}$ (depending only on $\lambda$ ) such that for all $n \geq n_{0}$ there exists a t-system of degree $n$ without long overlapping.
Proof. There are $2^{n(\lambda+1)} t$-systems of degree $n$ and every $t$-system can be described with $n(\lambda+1)$ bits. We show that if the $t$-system $\mathcal{R}=\left(r_{0}, \ldots, r_{\lambda}\right)$ has a long overlapping and $n$ is large enough, then $\mathcal{R}$ can be described with strictly less than $n(\lambda+1)$ bits. It follows that there is at least one $t$-system without long overlapping. We can distinguish the following four cases:
Case 1: for some $\alpha \in\{1,-1\}$ and some $0 \leq i, j \leq \lambda$ with $i \neq j, \pi_{t}\left(r_{i}^{\alpha}\right)$ and $\pi_{t}\left(r_{j}^{\alpha}\right)$ have a long overlapping, i.e., $\pi_{t}\left(r_{i}^{\alpha}\right)=x y, \pi_{t}\left(r_{j}^{\alpha}\right)=y z$, and $|y| \geq$ $\frac{\left|r_{i}\right|-\left|s_{11} x_{f} s_{11}\right|}{2}$. Thus, $r_{j}^{\alpha}$ can be reconstructed from the pair $(i, z)$ (note that the length of $y$ is fixed by $z$ ). Since $\lambda$ is a fixed constant, $i \in\{0, \ldots, \lambda\}$ can be specified by $O(1)$ many bits. Thus, in the description of $\mathcal{R}$ we can save at least $\frac{|y|}{|X|!}-O(1) \geq \frac{\left|r_{i}\right|-\left|s_{11} x_{f} s_{11}\right|}{2|X|!}-O(1)=\frac{(n+2)|X|!-\left|s_{11} x_{f} s_{11}\right|}{2|X|!}-O(1) \frac{n}{2}-O(1)$ many

[^1]bits. For a sufficiently large $n$, this term is strictly greater than 0 ; note that $\left|s_{11} x_{f} s_{11}\right|$ is a constant.

Case 2: for some $0 \leq i \leq \lambda, \pi_{t}\left(r_{i}\right)$ has a long overlapping with itself, i.e., $\pi_{t}\left(r_{i}\right)=x y=y z$, and $|y| \geq \frac{\left|r_{i}\right|-\left|s_{11} x_{f} s_{11}\right|}{2}$. It follows that $\pi_{t}\left(r_{i}\right)=x^{p} x^{\prime}$ for some $p>0$, where $x^{\prime}$ is a prefix of $x$. Thus, $r_{i}$ can be reconstructed from $x$. Hence, in the description of $\mathcal{R}$ we can save at least $\frac{\left|r_{i}\right|-\left|s_{11} x_{f} s_{11}\right|}{2|X|!}=\frac{n}{2}-O(1)$ many bits.

Case 3: for some $0 \leq i, j \leq \lambda$ with $i \neq j, \pi_{t}\left(r_{i}\right)$ and $\pi_{t}\left(r_{j}^{-1}\right)$ have a long overlapping. This case can be treated analogous to Case 1.

Case 4: for some $0 \leq i \leq \lambda, \pi_{t}\left(r_{i}\right)$ and $\pi_{t}\left(r_{i}^{-1}\right)$ have a long overlapping, i.e., $\pi_{t}\left(r_{i}\right)=x y, \pi_{t}\left(r_{i}^{-1}\right)=\pi_{t}\left(r_{i}\right)^{-1}=y z$, and $|y| \geq \frac{\left|r_{i}\right|-\left|s_{11} x_{f} s_{11}\right|}{2}$. From $\pi_{t}\left(r_{i}\right)^{-1}=y z$ we get $\pi_{t}\left(r_{i}\right)=z^{-1} y^{-1}=x y$, i.e., $y=y^{-1}$. But this means that the last $\left\lfloor\frac{|y|}{2}\right\rfloor$ many symbols in $y$ can be reconstructed from the first $\left\lceil\frac{|y|}{2}\right\rceil$ many symbols. Hence, in the description of $\mathcal{R}$ we can save at least $\frac{\left|r_{i}\right|-\left|s_{11} x_{f} s_{11}\right|}{4|X|!}-$ $O(1)=\frac{n}{4}-O(1)$ many bits.

We will use $\mathcal{R}$ to construct a sequence $s$, which can be replaced by the sequence $v_{1} \cdot k \cdot v_{2}$ in Lemma 3.13.

Let us fix a $t$-system $\mathcal{R}=\left(r_{0}, \ldots, r_{\lambda}\right)$ of degree $n$ without long overlapping, where moreover $n$ is chosen large enough such that

$$
\begin{equation*}
\forall w \in W:\left|r_{i-1} s_{11} x_{f} s_{11} r_{i}\right|>|w| \tag{12}
\end{equation*}
$$

For $1 \leq i \leq \lambda, u, v \in \operatorname{Red}\left(\left(H^{\prime}\right)_{k}^{f}, t\right)$, and $0 \leq j \leq|u|$ we write $u \xrightarrow{j}_{i} v$ if there exist $u_{1}, u_{2} \in \operatorname{Red}\left(\left(H^{\prime}\right)_{k}^{f}, t\right)$ and $\alpha \in\{1,-1\}$ such that

- $u=u_{1} \cdot\left(r_{i-1} s_{11} x_{f} s_{11} r_{i}\right)^{\alpha} \cdot u_{2}$,
- $v=u_{1} \cdot\left(r_{i-1} s_{11} k s_{11} r_{i}\right)^{\alpha} \cdot u_{2}$, and
- $\left|u_{1}\right|=j$.

We write $u \rightarrow_{i} v$ if there exist $0 \leq j \leq|u|$ such that $u{ }_{\rightarrow}^{j}{ }_{i} v$. Thus $\rightarrow_{i}$ can be seen as a string rewriting relation (see e.g. [1]), which is restriced to reduced $t$ sequences. In the notation $\xrightarrow{j}$ we also specify the position, where the rewriting step is carried out. We write $u \stackrel{j}{\Rightarrow}_{i} v$ if there exist $u^{\prime}, v^{\prime} \in \operatorname{Red}\left(\left(H^{\prime}\right)_{k}^{f}, t\right)$ such that $u \sim u^{\prime} \xrightarrow{j}_{i} v^{\prime} \sim v$, and we write $u \Rightarrow_{i} v$ if there exist $0 \leq j \leq|u|$ such that $u \stackrel{j}{\Rightarrow}_{i} v$. Clearly, the relation $\Rightarrow_{i}$ is terminating, i.e., there does not exist an infinite chain $u_{0} \Rightarrow_{i} u_{1} \Rightarrow_{i} u_{2} \Rightarrow_{i} \cdots$. Let $\operatorname{IRR}_{i}=\left\{u \mid \neg \exists v: u \Rightarrow_{i} v\right\}$. Note that $W \subseteq \operatorname{IRR}_{i}$ by (12). Moreover, $s \Rightarrow_{i} t$ implies also $s^{-1} \Rightarrow_{i} t^{-1}$.

Lemma 3.16. If $p_{i} \Leftarrow x \Rightarrow_{i} q$ then $p \sim q$ or there exists $w \in \operatorname{Red}\left(\left(H^{\prime}\right)_{k}^{f}, t\right)$ such that $p \Rightarrow_{i} w_{i} \Leftarrow q$.

Proof. Assume that

$$
\begin{equation*}
p_{i} \stackrel{j}{\leftarrow} u \sim v \stackrel{\ell}{\rightarrow}_{i} q, \tag{13}
\end{equation*}
$$

where w.l.o.g. $j \leq \ell$. We will show that either $p \sim q$ or there exists $w \in$ $\operatorname{Red}\left(\left(H^{\prime}\right)_{k}^{f}, t\right)$ such that $p \Rightarrow_{i} w_{i} \Leftarrow q$. This proves the lemma.

From (13) we obtain a diagram of the following form, where $\alpha, \beta \in\{1,-1\}$, the upper bow is $u$, and the lower bow is $v$ :

Case 1. $j=\ell$. Then $p_{i} \stackrel{j}{\leftarrow} u \sim v \stackrel{j}{\rightarrow}_{i} q$. We can distinguish on the values of $\alpha$ and $\beta$. This results in four different cases. We only consider the following two cases, the other two cases are symmetric:
Case $1.1 \alpha=1$ and $\beta=-1$. We obtain a diagram of the following kind:

But this is not possible, since $\mathcal{R}$ has no long overlapping and hence $r_{i-1}$ and $r_{i}^{-1}$ cannot be exactly opposite to each other in a diagram.

Case 1.2. $\alpha=\beta=1$. Together with Lemma 3.4 and the fact that act $\left[r_{i-1}, X\right]=$ $\operatorname{act}\left[r_{i}, X\right]=\operatorname{id}_{X}$ and $\operatorname{act}\left[x_{f}, X\right]=f$, we obtain a diagram of the following kind, where $c \in X$, the upper bow represents $u$ and the lower bow represents $v$ :

But due to the defining relations for the generator $k$ (namely $k^{-1} c k=f(c)$ for $c \in X)$ in $\left(H^{\prime}\right)_{k}^{f}$, we obtain also the following diagram:

Here, the upper bow is precisely $p$ and the lower bow is $q$ from (13). Thus, $p \sim q$.

Case 2. $j<\ell$. Diagram ( $\dagger$ ) together with Lemma 3.14 implies that $\ell-j \geq$ $\left|r_{i-1} s_{11} x_{f} s_{11}\right|$. Thus, the $x_{f}^{\alpha}$-segment in the upper bow of diagram ( $\dagger$ ) and the $x_{f}^{\beta}$-segment in the lower bow of diagram ( $\dagger$ ) are separated by a segment of length at least $\left|s_{11} r_{i} s_{11}\right|$, and the diagram ( $\dagger$ ) looks as follows, where $\left|u_{2}\right|=$ $\left|v_{2}\right| \geq\left|s_{11} r_{i} s_{11}\right|$ (we omit in this diagram the context $\left(r_{i-1} s_{11} \cdots s_{11} r_{i}\right)^{\alpha}$ around the $x_{f}^{\alpha}$-segment in the upper bow and analogously for the lower bow):

Let us assume $\alpha=\beta=1$ for simplicity. We obtain the derivations in Figure 1, where diagram (c) is diagram ( $\ddagger$ ) above. Note that the sequence in (e) is identical to the lower bow in diagram (a). It is important to note that in diagram (b), $\left|u_{2}\right| \geq\left|s_{11} r_{i}\right|$. This ensures that the context $u_{1} \cdots u_{2}$ around $x_{f}$ in the lower bow contains the context $r_{i-1} s_{11} \cdots s_{11} r_{i}$. This is crucial in order to carry out the reduction $u_{1} x_{f} u_{2}\left(c_{2} k c_{3}^{-1}\right) u_{3} \xrightarrow[\rightarrow]{j}_{i} u_{1} k u_{2}\left(c_{2} k c_{3}^{-1}\right) u_{3}$. The same remark applies to the context $v_{1} \cdots v_{2}$ around $x_{f}$ in diagram (d). This finishes the proof of the lemma.

By general results about rewriting systems modulo a congruence (see e.g. [3]), Lemma 3.16 implies:
 that $u \sim w$ or there exists $p \in \operatorname{Red}\left(\left(H^{\prime}\right)_{k}^{f}, t\right)$ such that $u \stackrel{*}{\Rightarrow}{ }_{i} p_{i} \stackrel{*}{\vee} w$.

Figure 1:

The previous lemma implies that for every $1 \leq i \leq \lambda$ and every sequence $u \in \operatorname{Red}\left(\left(H^{\prime}\right)_{k}^{f}, t\right)$, if $u \stackrel{*}{\Rightarrow}_{i} v \in \operatorname{IRR}_{i}$ and $u \stackrel{*}{\Rightarrow}_{i} w \in \operatorname{IRR}_{i}$, then $v \sim w$. Since the relation $\Rightarrow_{i}$ is terminating, there exists at least one $v \in \operatorname{IRR}_{i}$ with $u \stackrel{*}{\Rightarrow}_{i} v$. In the following, $\mathrm{NF}_{i}(u)$ denotes an arbitrary sequence with $u \stackrel{*}{\Rightarrow}{ }_{i} \mathrm{NF}_{i}(u) \in \mathrm{IRR}_{i}$; we only (w.l.o.g.) require that if $u$ starts (resp. ends) with $t^{\alpha}(\alpha \in\{1,-1\})$ then also $\mathrm{NF}_{i}(u)$ starts (resp. ends) with $t^{\alpha}$. This ensures that if the concatenation $u \cdot v$ of $u$ and $v$ is defined then also the concatenation $\mathrm{NF}_{i}(u) \cdot \mathrm{NF}_{i}(v)$ is defined. Note that the sequence $\mathrm{NF}_{i}(u)$ is unique up to $\sim$.

Lemma 3.18. For all $1 \leq i \leq \lambda$ we have:

- $\mathrm{NF}_{i}(w) \sim w$ for all $w \in W$,
- if $u \sim v^{-1}$ for $u, v \in \operatorname{Red}\left(H^{\prime}, t\right)$, then $\mathrm{NF}_{i}(u) \sim \mathrm{NF}_{i}(v)^{-1}$.

Proof. The first point follows from the fact that $W \subseteq \operatorname{IRR}_{i}$, see (12). For the second point note that $u \sim v^{-1}$ implies $\mathrm{NF}_{i}(u) \sim \mathrm{NF}_{i}\left(v^{-1}\right)$. Since $x \Rightarrow_{i} y$ implies $x^{-1} \Rightarrow_{i} y^{-1}$, we have $\mathrm{NF}_{i}\left(v^{-1}\right) \sim \mathrm{NF}_{i}(v)^{-1}$.

Lemma 3.19. Let $u, v, u^{\prime}, v^{\prime}, w \in \operatorname{Red}\left(\left(H^{\prime}\right)_{k}^{f}, t\right)$ such that

- the concatenations $u \cdot v$ and $u^{\prime} \cdot v^{\prime}$ are defined (as reduced $t$-sequences),
- $\left(u^{\prime} \rightarrow_{i} u\right.$ and $\left.v^{\prime}=v\right)$ or $\left(v^{\prime} \rightarrow_{i} v\right.$ and $\left.u^{\prime}=u\right)\left(\right.$ thus, $\left.u^{\prime} \cdot v^{\prime} \rightarrow_{i} u \cdot v\right)$,
- $u \cdot v \stackrel{j}{\Rightarrow}_{i} w$, and
- $0<|u|-j<\left|r_{i-1} s_{11} x_{f} s_{11} r_{i}\right|$.

Then there exists $w^{\prime} \in \operatorname{Red}\left(\left(H^{\prime}\right){ }_{k}^{f}, t\right)$ and $j^{\prime} \in \mathbb{N}$ such that $u^{\prime} \cdot v^{\prime}{\stackrel{j^{\prime}}{\Rightarrow}}_{i} w^{\prime}$ and $\left|u^{\prime}\right|-j^{\prime}=|u|-j$.

Proof. Let us assume that $u^{\prime} \rightarrow_{i} u$ and $v^{\prime}=v$, the other case is only simpler. Since $u^{\prime} \rightarrow_{i} u$, there exists a factorization $u^{\prime}=u_{1}\left(r_{i-1} s_{11} x_{f} s_{11} r_{i}\right)^{\alpha} u_{2}$ and $u=u_{1}\left(r_{i-1} s_{11} k s_{11} r_{i}\right)^{\alpha} u_{2}$. Together with $u \cdot v \stackrel{j}{\Rightarrow}_{i} w$ and $0<|u|-j<$ $\left|r_{i-1} s_{11} x_{f} s_{11} r_{i}\right|$ we obtain a diagram of the following form, where $\beta \in\{1,-1\}$ and $c \in A \cup B$ :

Note that $0<|u|-j<\left|r_{i-1} s_{11} x_{f} s_{11} r_{i}\right|$ means that the end point of the vertical $c$-edge lies strictly within the segment $\left(r_{i-1} s_{11} x_{f} s_{11} r_{i}\right)^{\beta}$ of the lower bow.

Lemma 3.14 implies that the segment $\left(r_{i-1} s_{11} k s_{11} r_{i}\right)^{\alpha}$ in the upper bow overlaps the segment $\left(r_{i-1} s_{11} x_{f} s_{11} r_{i}\right)^{\beta}$ in the lower bow by at most $\left|r_{i-1}\right|=\left|r_{i}\right|$ (these two segments cannot be exactly opposite to each other, since the segment $\left(r_{i-1} s_{11} k s_{11} r_{i}\right)^{\alpha}$ in the upper bow is completely contained in the left factor $u$ but the segment $\left(r_{i-1} s_{11} x_{f} s_{11} r_{i}\right)^{\beta}$ in the lower bow contains the end point of the vertical $c$-edge). Thus, the above diagram looks in fact as follows, where we omit the context $\left(r_{i-1} s_{11} \cdots s_{11} r_{i}\right)^{\alpha}$ in the rewriting step within $u$ :

Here $v=v_{1} v_{2}$ and

$$
\begin{aligned}
u_{1}^{\prime} & = \begin{cases}u_{1} r_{i-1} s_{11} & \text { if } \alpha=1 \\
u_{1} r_{i}^{-1} s_{11}^{-1} & \text { if } \alpha=-1\end{cases} \\
x \cdot u_{2}^{\prime} & = \begin{cases}s_{11} r_{i} u_{2} & \text { if } \alpha=1 \\
s_{11}^{-1} r_{i-1}^{-1} u_{2} & \text { if } \alpha=-1\end{cases}
\end{aligned}
$$

The existence of the sequences $x$ and $y$ follows from Lemma 3.14. Moreover, $u=u_{1}^{\prime} k^{\alpha} x u_{2}^{\prime}$ and $j=\left|u_{1}^{\prime} k^{\alpha} x\right|$ and hence $|u|-j=\left|u_{2}^{\prime}\right|$. By replacing $k^{\alpha}$ by $x_{f}^{\alpha}$, we get the following diagram:

which shows that there exist $w^{\prime}$ and $j^{\prime}$ with $u_{1}^{\prime} x_{f}^{\alpha} x u_{2}^{\prime} v_{1} v_{2}=u^{\prime} v=u^{\prime} v^{\prime}{\stackrel{j^{\prime}}{\Rightarrow}}_{i} w^{\prime}$. Moreover, $u^{\prime}=u_{1}^{\prime} x_{f}^{\alpha} x u_{2}^{\prime}$ and $j^{\prime}=u_{1}^{\prime} x_{f}^{\alpha} x$, and hence $\left|u^{\prime}\right|-j^{\prime}=\left|u_{2}^{\prime}\right|=|u|-j$. This proves the lemma.

By Lemma 3.18, every normal form mapping $\mathrm{NF}_{i}$ preserves sequences from $W$ and the inverse mapping ${ }^{-1}$ modulo $\sim$. On the other hand, concatenation on $\operatorname{Red}\left(H^{\prime}, t\right)$ is in general not preserved, but the following statement will suffice:

Lemma 3.20. Let $v, w \in \operatorname{Red}\left(H^{\prime}, t\right)$ such that $v \cdot w$ is defined (as a reduced $t$-sequence). There are at most two $i \in\{1, \ldots, \lambda\}$ with $\mathrm{NF}_{i}(v) \cdot \mathrm{NF}_{i}(w) \nsim$ $\mathrm{NF}_{i}(v \cdot w)$.

Proof. Since $\Rightarrow_{i}$ is confluent modulo $\sim$ we have $v \cdot w \stackrel{*}{\Rightarrow}{ }_{i} \mathrm{NF}_{i}(v) \cdot \mathrm{NF}_{i}(w) \stackrel{{ }^{*}}{i}$ $x \sim \mathrm{NF}_{i}(v \cdot w)$ for some $x$. Now assume that $\mathrm{NF}_{i}(v) \cdot \mathrm{NF}_{i}(w) \nsim \mathrm{NF}_{i}(v \cdot w)$. Thus, $v \cdot w \stackrel{*}{\Rightarrow}_{i} \mathrm{NF}_{i}(v) \cdot \mathrm{NF}_{i}(w) \stackrel{j}{\Rightarrow}_{i} z$ for some position $j$ and some sequence z. If $j \geq\left|\mathrm{NF}_{i}(v)\right|$, then we would have $\mathrm{NF}_{i}(w) \notin \mathrm{IRR}_{i}$. Similarly, if $j \leq$ $\left|\mathrm{NF}_{i}(v)\right|-\left|r_{i-1} s_{11} x_{f} s_{11} r_{i}\right|$, then $\mathrm{NF}_{i}(v) \notin \operatorname{IRR}_{i}$. Thus, we obtain $0<\left|\mathrm{NF}_{i}(v)\right|-$ $j<\left|r_{i-1} s_{11} x_{f} s_{11} r_{i}\right|$. By applying Lemma 3.19 to every rewriting step in the derivations $v \stackrel{*}{\Rightarrow}_{i} \mathrm{NF}_{i}(v)$ and $w \stackrel{*}{\Rightarrow}_{i} \mathrm{NF}_{i}(w)$, it follows that $v \cdot w{\stackrel{j^{\prime}}{\Rightarrow}}_{i} z^{\prime}$ for some sequence $z^{\prime}$ and some position $j^{\prime}$ such that $0<|v|-j^{\prime}<\left|r_{i-1} s_{11} x_{f} s_{11} r_{i}\right|$.

Now assume that there are three different $i_{1}, i_{2}, i_{3} \in\{1, \ldots, \lambda\}$ such that $\mathrm{NF}_{i_{\ell}}(v) \cdot \mathrm{NF}_{i_{\ell}}(w) \nsim \mathrm{NF}_{i_{\ell}}(v \cdot w)$ for $\ell \in\{1,2,3\}$. By the above consideration, we obtain $v \cdot w{\stackrel{j_{\ell}}{\Rightarrow}}_{i_{\ell}} z_{\ell}$ for sequences $z_{1}, z_{2}, z_{3}$ and positions $j_{1}, j_{2}, j_{3}$ such that $0<|v|-j_{\ell}<\left|r_{i-1} s_{11} x_{f} s_{11} r_{i}\right|$. W.l.o.g. assume that $j_{1} \leq j_{2} \leq j_{3}$. Then either $j_{2}-j_{1}<\frac{\left|r_{i-1} s_{11} x_{f} s_{11} r_{i}\right|}{2}$ or $j_{3}-j_{2}<\frac{\left|r_{i-1} s_{11} x_{f} s_{11} r_{i}\right|}{2}$. W.l.o.g. assume that $j_{2}-j_{1}<\frac{\left|r_{i-1} s_{11} x_{f} s_{11} r_{i}\right|}{2}$. Lemma 3.14 implies $j_{2}=j_{1}$. But with $i_{1} \neq i_{2}$ this leads to a contradiction.

Recall that $\lambda$ was chosen to be larger than $2 d$, where $d$ is the number of atomic propositions of the form $x \cdot y \sim z$ that occur in our boolean formula $\chi$.

Lemma 3.21. Let $x_{j}, y_{j}, z_{j} \in \operatorname{Red}\left(H^{\prime}, t\right)$ for $1 \leq j \leq d$. Then there exists $1 \leq i \leq \lambda$ such that for all $1 \leq j \leq d, x_{j} \cdot y_{j} \sim z_{j}$ if and only if $\mathrm{NF}_{i}\left(x_{j}\right)$. $\mathrm{NF}_{i}\left(y_{j}\right) \sim \mathrm{NF}_{i}\left(z_{j}\right)$.
Proof. The "only if"-direction follows from Lemma 3.20 and the fact that $\lambda>$ $2 d$, where $d$ is the number of equations in the formula $\chi$. For the "if"-direction assume that $\mathrm{NF}_{i}\left(x_{j}\right) \cdot \mathrm{NF}_{i}\left(y_{j}\right) \sim \mathrm{NF}_{i}\left(z_{j}\right)$. Thus, $\mathrm{NF}_{i}\left(x_{j}\right) \cdot \mathrm{NF}_{i}\left(y_{j}\right) \in \mathrm{IRR}_{i}$, which implies $\mathrm{NF}_{i}\left(x_{j} \cdot y_{j}\right) \sim \mathrm{NF}_{i}\left(x_{j}\right) \cdot \mathrm{NF}_{i}\left(y_{j}\right) \sim \mathrm{NF}_{i}\left(z_{j}\right)$. Hence, it suffices to show that $\operatorname{NF}_{i}(u) \sim \mathrm{NF}_{i}(v)$ for $u, v \in \operatorname{Red}\left(H^{\prime}, t\right)$ implies $u \sim v$. For this, define a morphism $\sigma:\left(H^{\prime}\right)_{k}^{f} \rightarrow H^{\prime}$ by $\sigma(k)=x_{f}$ and $\sigma(x)=x$ for all $x \in H^{\prime}$, which is well-defined. This morphism can be extended to a mapping $\sigma: \operatorname{Red}\left(\left(H^{\prime}\right)_{k}^{f}, t\right) \rightarrow$ $\operatorname{Red}\left(H^{\prime}, t\right)$ in the natural way. Note that $p \sim q\left(\right.$ for $\left.p, q \in \operatorname{Red}\left(\left(H^{\prime}\right)_{k}^{f}, t\right)\right)$ implies $\sigma(p) \sim \sigma(q)$.

We claim that $p \Rightarrow_{i} q\left(\right.$ for $\left.p, q \in \operatorname{Red}\left(\left(H^{\prime}\right)_{k}^{f}, t\right)\right)$ implies $\sigma(p) \sim \sigma(q)$. If $p \Rightarrow_{i} q$ then there exist $p^{\prime}, q^{\prime}$ such that $p \sim p^{\prime} \rightarrow_{i} q^{\prime} \sim q$. This implies $\sigma(p) \sim$ $\sigma\left(p^{\prime}\right)=\sigma\left(q^{\prime}\right) \sim \sigma(q)$, i.e., $\sigma(p) \sim \sigma(q)$.

Now assume that $\mathrm{NF}_{i}(u) \sim \mathrm{NF}_{i}(v)$ for $u, v \in \operatorname{Red}\left(H^{\prime}, t\right)$. Since $u \Rightarrow_{i}^{*} \mathrm{NF}_{i}(u)$ and $v \Rightarrow_{i}^{*} \mathrm{NF}_{i}(v)$, we obtain $u=\sigma(u) \sim \sigma\left(\mathrm{NF}_{i}(u)\right) \sim \sigma\left(\mathrm{NF}_{i}(v)\right) \sim \sigma(v)=$ $v$.

Now we are able to prove Lemma 3.13: Assume that

$$
\forall x \in\{s \in \operatorname{Red}(H, t) \mid \operatorname{act}[s, X]=f\} \exists y_{1} \cdots \exists y_{m}\left\{\begin{array}{l}
\bigwedge_{1 \leq i \leq m} y_{i} \in \operatorname{Red}\left(H_{i}, t\right) \\
\wedge \chi\left(x, y_{1}, \ldots, y_{m}, \widetilde{w}\right)
\end{array}\right\}
$$

in $\operatorname{Red}\left(H^{\prime}, t\right)$. Let

$$
s=r_{0} s_{11} x_{f} s_{11} r_{1} s_{11} x_{f} s_{11} r_{2} \cdots s_{11} x_{f} s_{11} r_{\lambda-1} s_{11} x_{f} s_{11} r_{\lambda} \in \operatorname{Red}(H, t) .
$$

Note that $\operatorname{act}[s, X]=\operatorname{act}\left[x_{f}, X\right]^{\lambda}=\operatorname{act}\left[x_{f}, X\right]=f$ since $\lambda-1$ is a multiple of $|X|$ !. Thus, there exist sequences $t_{i} \in \operatorname{Red}\left(H_{i}, t\right)(1 \leq i \leq m)$ with $\chi\left(s, t_{1}, \ldots, t_{m}, \widetilde{w}\right)$ in $\operatorname{Red}\left(H^{\prime}, t\right)$. By Lemma 3.18 and Lemma 3.21 there exists $1 \leq j \leq \lambda$ such that $\chi\left(\mathrm{NF}_{j}(s), \mathrm{NF}_{j}\left(t_{1}\right), \ldots, \mathrm{NF}_{j}\left(t_{m}\right), \widetilde{w}\right)$ in the structure $\operatorname{Red}\left(\left(H^{\prime}\right)_{k}^{f}, t\right)$. Moreover, we have $\mathrm{NF}_{j}\left(t_{i}\right) \in \operatorname{Red}\left(\left(H_{i}\right)_{k}^{f}, t\right)$. Since $\mathcal{R}$ has no long overlapping, there exists exactly one occurrence of $r_{j-1} s_{11} x_{f} s_{11} r_{j}$ in every sequence which is $\sim$-equivalent to $s$. Hence, we can write $s=v_{1} \cdot x_{f} \cdot v_{2}$ and $\mathrm{NF}_{j}(s) \sim v_{1} \cdot k \cdot v_{2}$ for $v_{1}, v_{2} \in \operatorname{Red}(H, t)$. Thus,

$$
\begin{aligned}
f=\operatorname{act}[s, X] & =\operatorname{act}\left[v_{1} \cdot x_{f} \cdot v_{2}, X\right]= \\
& \operatorname{act}\left[v_{1}, X\right] \circ \operatorname{act}\left[x_{f}, X\right] \circ \operatorname{act}\left[v_{2}, X\right]=\operatorname{act}\left[v_{1}, X\right] \circ f \circ \operatorname{act}\left[v_{2}, X\right]
\end{aligned}
$$

and

$$
\exists y_{1} \cdots \exists y_{m}\left\{\begin{array}{l}
\bigwedge_{1 \leq i \leq m} y_{i} \in \operatorname{Red}\left(\left(H_{i}\right)_{k}^{f}, t\right) \\
\wedge \chi\left(v_{1} \cdot k \cdot v_{2}, y_{1}, \ldots, y_{m}, \widetilde{w}\right)
\end{array}\right\} \quad \text { in } \operatorname{Red}\left(\left(H^{\prime}\right)_{k}^{f}, t\right)
$$

This finishes the proof of Lemma 3.13.

## 4 Amalgamated free products

In this section we consider positive theories of amalgamated free products. Let us fix throughout Section 4 two groups $H$ and $J$ where $A=H \cap J$ is a proper subgroup of both $H$ and $J$. Let

$$
\begin{equation*}
G=H *_{A} J \tag{14}
\end{equation*}
$$

The aim of this section is to prove the following result:
Theorem 4.1. Let $G=H *_{A} J$ be an amalgamated free product, where $A=$ $H \cap J$ is a proper subgroup of both $H$ and $J$ and such that $A$ is finite. If $\mathrm{Th}_{\exists+}(G)$ is decidable, then $\mathrm{Th}_{+}(G)$ is decidable.

Remark 4.2. Note that Theorem 3.1 cannot be extended by allowing monoids for $H$ and $J$, since already the $\forall \exists \exists^{3}$-theory of the free monoid $\{a, b\}^{*}$ is undecidable [7, 18].

Let us first consider a special case of Theorem 4.1, namely the case that the index of $A$ in $H$ and $J$ is both $2:[H: A]=[J: A]=2$. In this case, $G=H *_{A} J$ has $\mathbb{Z}$ as a subgroup of finite index [2, p. 31], hence, the whole first-order theory of $G$ is decidable [8]. Thus, we may assume that either $[H: A] \geq 3$ or $[J: A] \geq 3$ in the following. W.l.o.g. we assume for the rest of Section 4 that $[J: A] \geq 3$.

### 4.1 Reduced $(H, J)$-sequences

Recall from [14] that an $(H, J)$-sequence is an element from the free product $H * J$. Similarly to HNN-extensions, elements from $H *_{A} J$ can be represented by certain reduced sequences: An $(H, J)$-sequence $s$ is reduced if either $s \in A$ or $s$ does not contain a factor from $A$. Alternatively, we can view a reduced $t$-sequence as a word from the language $\operatorname{Red}(H, J)=A \cup \Gamma^{*} \backslash \Gamma^{*}\{x y \mid x, y \in$ $H$ or $x, y \in J\} \Gamma^{*}$, where $\Gamma=(H \cup J) \backslash A$. For $u, v, w \in \operatorname{Red}(H, J)$ we write $u \cdot v=w$ if and only if $u v=w$ as words over the alphabet $\Gamma$. In this case, we also say that the concatenation $u \cdot v$ of $u$ and $v$ is defined. With $\sim$ we denote the smallest congruence on $H * J$ containing all pairs $(j(a h),(j a) h)$ and $(h(a j),(h a) j)$ for $a \in A, h \in H$, and $j \in J$. Then $u, v \in \operatorname{Red}(H, J)$ represent the same element of the amalgamated free product $G$ if and only if $u \sim v$ [14]. Equivalently, if

$$
\begin{align*}
u & =h_{0} j_{1} h_{1} j_{2} \cdots h_{n-1} j_{n} h_{n} \text { and }  \tag{15}\\
v & =h_{0}^{\prime} j_{1}^{\prime} h_{1}^{\prime} j_{2}^{\prime} \cdots h_{m-1}^{\prime} j_{m}^{\prime} h_{m}^{\prime} \tag{16}
\end{align*}
$$

(with $n, m \geq 0, h_{0}, \cdots h_{n}, h_{0}^{\prime}, \ldots, h_{m}^{\prime} \in H$, and $j_{1}, \cdots j_{n}, j_{1}^{\prime}, \ldots, j_{m}^{\prime} \in J$ ) are reduced $(H, J)$-sequences, then $u \sim v$ if and only if $n=m$ and there exist $a_{1}, \ldots, a_{2 n} \in A$ such that:

- $h_{i} a_{2 i+1}=a_{2 i} h_{i}^{\prime}$ in $H$ for $0 \leq i \leq n$ (here we set $\left.a_{0}=a_{2 n+1}=1\right)$
- $j_{i} a_{2 i}=a_{2 i-1} j_{i}^{\prime}$ in $J$ for $1 \leq i \leq n$

In other words, there exists a Van Kampen diagram of the following kind:

As for HNN-extensions, the elements $a_{i}$ are called the connecting elements and occasionally we will omit in diagrams some of the connecting elements.

For the above $u \in \operatorname{Red}(H, J)$ in (15) let $u^{-1}=h_{n}^{-1} j_{n}^{-1} h_{n-1}^{-1} \cdots j_{2}^{-1} h_{1}^{-1} j_{1}^{-1} h_{0}^{-1}$. The length $|u|$ of $u \in \operatorname{Red}(H, J)$ is the number of occurences of letters from $(H \cup J) \backslash A$ in the sequence $u$. As for reduced $t$-sequences in the case of HNNextensions, $u \sim v$ implies $|u|=|v|$. We identify the set $\operatorname{Red}(H, J)$ with the relational structure that contains the following predicates and constants:

- the ternary relation $\{(u, v, w) \mid u \cdot v \sim w\}$
- the ternary relation $\{(u, v, w) \mid u, v, w \in H, u v=w$ in $H\}$
- the ternary relation $\{(u, v, w) \mid u, v, w \in J, u v=w$ in $J\}$
- the binary relation $\left\{(u, v) \mid u \sim v^{-1}\right\}$
- every element of $\operatorname{Red}(H, J)$ as a constant

We will use the following lemma from [13]:
Lemma 4.3. For a given boolean combination $\phi\left(x_{1}, \ldots, x_{n}\right)$ of word equations over the amalgamated free product $G$ we can effectively construct an existential formula $\exists y_{1} \cdots \exists y_{m}: \chi\left(x_{1}, \ldots, x_{n}, y_{1}, \ldots, y_{m}\right)$ over the structure $\operatorname{Red}(H, J)$ such that for all $s_{1}, \ldots, s_{n} \in \operatorname{Red}(H, J)$ we have:
$\phi\left(s_{1}, \ldots, s_{n}\right)$ in $G \Leftrightarrow \exists y_{1} \cdots \exists y_{m}: \chi\left(x_{1}, \ldots, x_{n}, y_{1}, \ldots, y_{m}\right)$ in $\operatorname{Red}(H, J)$
(here, when writing $\phi\left(s_{1}, \ldots, s_{n}\right)$ in $G$, we identify $s_{i} \in \operatorname{Red}(H, J)$ with the element from $G$ it represents).

### 4.2 The finite normal subgroup $X$ and stabilizing sequences

Analogously to Section 3.2 we define stabilizing reduced $(H, J)$-sequences and a normal finite subgroup $X$ of $A$ in this section.

For a subgroup $X \leq A$ and $g \in G$ we define a partial automorphism $\operatorname{act}[g, X]: X \rightarrow_{p} X$ by conjugation: $\operatorname{act}[g, X](y)=z$ if and only if $y, z \in X$ and $g^{-1} y g=z$. For a reduced $(H, J)$-sequence $u$, act $[u, X]$ is defined as act $[g, X]$, where $g$ is the element of $G$ represented by $u$. The goal of this section is to prove the following lemma:

Lemma 4.4. There exists a finite subgroup $X \leq A$ and there exist sequences $s_{H H}, s_{J J}, s_{J H}, s_{H J} \in \operatorname{Red}(H, J)$ such that

- $s_{\alpha \beta} \in(\alpha \backslash A) \cdot \operatorname{Red}(H, J) \cdot(\beta \backslash A)$,
- $X$ is a normal subgroup of $G$, i.e., for all $g \in G$ : $\operatorname{act}[g, X]$ is an (totally defined) automorphism of $X$, and
- for all $a, b \in A$, if $a s_{\alpha \beta}=s_{\alpha \beta} b$ in $G$ then $a=b \in X$.

Recall that we assume $[J: A] \geq 3$ and that $A$ is finite. For reasons, which will become clear in Section 4.3, we will assume the following weaker restriction in this Section 4.2:

$$
\begin{equation*}
[J: A] \geq 3 \text { and } \exists h \in H \backslash A: A \cap h A h^{-1} \text { is finite } \tag{17}
\end{equation*}
$$

Choose an arbitrary $j \in J \backslash A$ and let

$$
\begin{equation*}
j^{\prime} \in J \backslash\left(A \cup j^{-1} A\right), \tag{18}
\end{equation*}
$$

which exists since $[J: A] \geq 3$. Next, let $h \in H \backslash A$ such that

$$
Y=A \cap h A h^{-1}
$$

is finite, which exists by assumption. Note that $a h=h b$ for $a, b \in A$ implies $a \in Y$.

We will first construct the sequences $s_{J H}$ and $s_{H J}$ together with the normal and finite subgroup $X \leq A$. We will construct the subgroup $X$ as the limit of a decreasing chain $Y \supseteq X_{0} \supsetneq X_{1} \supsetneq X_{2} \cdots$. Let act $=\operatorname{act}[h j, Y]$ and define the subgroup

$$
X_{0}=\left\{x \in Y \mid \forall k \geq 0: \operatorname{act}^{k}(x) \text { is defined }\right\} .
$$

The restriction $\operatorname{act}{ }_{X_{0}}$ is a permutation on the finite subgroup $X_{0}$. Hence we can fix a number $n \in \mathbb{N}$ such that $n>|Y|$ and $\left(\left.\operatorname{act}\right|_{X_{0}}\right)^{n}=\operatorname{id}_{X_{0}}$.

Lemma 4.5. For all $a, b \in A$, if $a(h j)^{n}=(h j)^{n} b$ in $G$ then $a=b \in X_{0}$.
Proof. Assume that $a(h j)^{n}=(h j)^{n} b$ in $G$ for some $a, b \in A$, i.e., $(a h) j(h j)^{n-1}=$ $(h j)^{n-1} h(j b)$. Since $(a h) j(h j)^{n-1}$ and $(h j)^{n-1} h(j b)$ are reduced $(H, J)$-sequences, we obtain a Van Kampen diagram of the following kind:

We get $a_{0}, \ldots, a_{n-1} \in Y, \operatorname{act}\left(a_{i}\right)=a_{i+1}$ for $0 \leq i<n-1$, and act $[h j, A]\left(a_{n-1}\right)=$ $a_{n}$. Since $n>|Y|$ there are $0 \leq i<j \leq n-1$ such that $a_{i}=a_{j}$, i.e., act enters a cycle at $a_{i}$ and $a_{i} \in X_{0}$. Since $X_{0}$ is closed under act and act ${ }^{-1}$, we obtain $a, a_{1}, \ldots, a_{n-1}, b \in X_{0}$. Moreover, $\left(\operatorname{act} \Gamma_{X_{0}}\right)^{n}=\operatorname{id}_{X_{0}}$ implies $a=b$.

Let $s_{0}^{H J}=(h j)^{n}$ and $s_{0}^{J H}=\left(j^{-1} h^{-1}\right)^{n}$. Next we define $s_{i}^{J H}, s_{i}^{H J} \in \operatorname{Red}(H, J)$ and a subgroup $X_{i} \leq Y$ for larger $i$ inductively:

Assume that for some $i \geq 0$, reduced $(H, J)$-sequences $s_{i}^{J H}, s_{i}^{H J} \in \operatorname{Red}(H, J)$ and a finite subgroup $X_{i} \leq A$ with the following properties are already defined:

- $s_{i}^{\alpha \beta} \in(\alpha \backslash A) \cdot \operatorname{Red}(H, J) \cdot(\beta \backslash A)$
- for all $a, b \in A$, if $a s_{i}^{\alpha \beta}=s_{i}^{\alpha \beta} b$ in $G$ then $a=b \in X_{i}$

If for all $g \in G, \operatorname{act}\left[g, X_{i}\right]$ is totally defined, then we stop and set $s_{\alpha \beta}=s_{i}^{\alpha \beta}$ and $X=X_{i}$. Otherwise there exists $g \in G$ such that act $\left[g, X_{i}\right]$ is not totally defined on $X_{i}$. We can assume that $g \in(H \cup J) \backslash A .^{3}$ Hence, we can choose elements $h_{0} \in H \backslash A$ and $j_{0} \in J \backslash A$ such that either act $\left[h_{0}, X_{i}\right]$ is not totally defined on $X_{i}$ or act $\left[j_{0}, X_{i}\right]$ is not totally defined on $X_{i}$.

Let $s=s_{i}^{H J} h_{0} s_{i}^{J H} j_{0} s_{i}^{H J} \in \operatorname{Red}(H, J)$ and let act $=\operatorname{act}\left[s, X_{i}\right]$. If act $\left[h_{0}, X_{i}\right]$ is not totally defined on $X_{i}$, then $\operatorname{dom}($ act $) \subsetneq X_{i}$ and if act $\left[j_{0}, X_{i}\right]$ is not totally defined on $X_{i}$, then $\operatorname{ran}($ act $) \subsetneq X_{i}$. Hence, act is not totally defined on $X_{i}$. Define

$$
X_{i+1}=\left\{x \in X_{i} \mid \forall k \geq 0: \operatorname{act}^{k}(x) \text { is defined }\right\}<X_{i} .
$$

Clearly, act $\prod_{X_{i+1}}$ is a permutation on $X_{i+1}$. Let $m$ be such that $m+1>\left|X_{i}\right|$ and $\left(\operatorname{act} \Gamma_{X_{i+1}}\right)^{m}=\operatorname{id}_{X_{i+1}}$, and define

$$
s_{i+1}^{H J}=s^{m} .
$$

The sequence $s_{i+1}^{J H}$ is constructed similarly, we only have to take $s_{i+1}^{H J}=s^{m}$ for $s=s_{i}^{J H} j_{0} s_{i}^{H J} h_{0} s_{i}^{J H} \in \operatorname{Red}(H, J)$. By construction we have $s_{i+1}^{\alpha \beta} \in(\alpha \backslash A)$. $\operatorname{Red}(H, J) \cdot(\beta \backslash A)$.

Lemma 4.6. For all $a, b \in A$ and $\alpha \beta \in\{J H, H J\}$, if a $s_{i+1}^{\alpha \beta}=s_{i+1}^{\alpha \beta} b$ in $G$, then $a=b \in X_{i+1}$.

Proof. We restrict to the case that $\alpha \beta=H J$, the other case can be dealt analogously. Assume that we have $a, b \in A$ with

$$
a\left(s_{i}^{H J} h_{0} s_{i}^{J H} j_{0} s_{i}^{H J}\right)^{m}=\left(s_{i}^{H J} h_{0} s_{i}^{J H} j_{0} s_{i}^{H J}\right)^{m} b \text { in } G .
$$

We obtain a diagram of the following form, where $a_{0}=a, a_{2 m}=b$, and $a_{0}, a_{1}, \ldots, a_{2 m} \in X_{i}$ due to the assumptions on $s_{i}^{H J}$ and $s_{i}^{J H}$ :

[^2]Hence, $\operatorname{act}\left(a_{2 i}\right)=a_{2 i+2}$ for $0 \leq i<m$. Since $m+1>\left|X_{i}\right|$, there are $i<j$ with $a_{2 i}=a_{2 j}$. Thus, act enters a cycle at $a_{2 i}$, i.e., $a_{2 i} \in X_{i+1}$. But since $X_{i+1}$ is closed under act and act $^{-1}$, we get $a, a_{2}, \ldots, a_{2(m-1)}, b \in X_{i+1}$. Moreover, $\left(\operatorname{act}\left\lceil_{X_{i+1}}\right)^{m}=\operatorname{id}_{X_{i+1}}\right.$ implies $a=b$.

This concludes the construction of the sequences $s_{H J}$ and $s_{J H}$ as well as the normal finite subgroup $X \leq A$. In order to construct $s_{H H}$ note that $s_{H J}=s \cdot j$ for some sequence $s$ and that $j^{\prime}$ was chosen in (18) such that $j^{\prime} \in J \backslash\left(A \cup j^{-1} A\right)$, i.e., $j j^{\prime} \notin A$. Now define

$$
s_{H H}=s_{H J} s\left(j j^{\prime}\right) h\left(j^{\prime} h\right)^{|X|!-1} s_{J H} \in(H \backslash A) \cdot \operatorname{Red}(H, J) \cdot(H \backslash A) .
$$

In the group $G$, this sequence equals $s_{H J} s_{H J}\left(j^{\prime} h\right)^{|X|!} s_{J H}$. Now assume that $a s_{H H}=s_{H H} b$ in $G$ for some $a, b \in A$. We have to show that $a=b \in X$. From $a s_{H H}=s_{H H} b$ and the properties of $s_{H J}$ and $s_{J H}$ we obtain the following Van Kampen diagram, where $a, b \in X$.

Moreover, we have $b=\operatorname{act}\left[s_{H H}, X\right](a)=\operatorname{act}\left[s_{H J} s_{H J}\left(j^{\prime} h\right)^{|X|!} s_{J H}, X\right](a)=a$.
Finally, it remains to construct $s_{J J}$. We set

$$
s_{J J}=s_{J H} j^{\prime}\left(s_{H H}\left(j j^{\prime}\right)\right)^{|X!|-1} s_{H H} j s_{H J} \in(J \backslash A) \cdot \operatorname{Red}(H, J) \cdot(J \backslash A),
$$

which is a reduced $(H, J)$-sequence, since $j j^{\prime} \in J \backslash A$. Note that act $\left[s_{J J}, X\right]=$ $\operatorname{act}\left[s_{J H}\left(j^{\prime} s_{H H} j\right)^{|X!|} s_{H J}, X\right]=\operatorname{id}_{X}$. This concludes the proof of Lemma 4.4.

### 4.3 Reducing to the existential positive theory

The reduction of the positive theory of the amalgamated free product $G=$ $H *_{A} J$ to the existential positive theory of $G$ is very similar to the case of an HNN-extension in Section 3.3: Given a positive sentence $\theta$, which is interpreted over $G$, we construct an existential positive sentence $\theta^{\prime}$, which is interpreted over a multiple HNN-extension $\mathbb{G}$ of $G$, where only finite subgroups of $A \leq G$ are associated (in fact, $X \subseteq A$ from Lemma 4.4 will be associated with itself).

Let us fix a formula

$$
\theta(\widetilde{z}) \equiv \forall x_{1} \exists y_{1} \cdots \forall x_{n} \exists y_{n} \phi\left(x_{1}, \ldots, y_{n}, y_{1}, \ldots, y_{n}, \widetilde{z}\right)
$$

with $\phi$ a positive boolean combination of word equations (with constants) over the group $G$. Let $X \leq A$ be the subgroup from Lemma 4.4. Recall that with $\operatorname{In}(X, G)$ we denote the group of all automorphisms $f$ of $X$ such that for some $g \in G$ we have: $f(c)=g^{-1} c g$ for all $c \in X$. In the following, we use the abbreviation $\operatorname{In}=\operatorname{In}(X, G)$.

The following theorem yields the reduction from the positive to the existential positive theory; $k_{1}, \ldots, k_{n} \notin G$ are new constants.

Theorem 4.7. Let $\theta(\widetilde{z}) \equiv \forall x_{1} \exists y_{1} \cdots \forall x_{n} \exists y_{n} \phi\left(x_{1}, \ldots, x_{n}, y_{1}, \ldots, y_{n}, \widetilde{z}\right)$ be as above. For all $\widetilde{u} \in G$ we have $\theta(\widetilde{u})$ in $G$ if and only if

$$
\bigwedge_{f_{1} \in \operatorname{In}} \exists y_{1} \cdots \bigwedge_{f_{n} \in \operatorname{In}} \exists y_{n}\left\{\begin{array}{l}
\bigwedge_{1 \leq i \leq n} y_{i} \in G_{k_{1}, \ldots, k_{i}}^{f_{1}, \ldots, f_{i}} \wedge  \tag{19}\\
\phi\left(k_{1}, \ldots, k_{n}, y_{1}, \ldots, y_{n}, \widetilde{u}\right)
\end{array}\right\} \text { in } G_{k_{1}, \ldots, k_{n}}^{f_{1}, \ldots, f_{n}}
$$

Theorem 4.7 will be deduced completely analogous to Theorem 3.10. The only new ingredient will be the proof of Lemma 4.8 below, which corresponds to Lemma 3.13.

Fix a number $m \in \mathbb{N}$, groups $H_{1}, \ldots, H_{m}, H^{\prime}$ such that $H \subseteq H_{i} \subseteq H^{\prime}$ and $H_{i} \cap J=H^{\prime} \cap J=H \cap J=A$ for $1 \leq i \leq m$. Let $G_{i}=H_{i} *_{A} J$ and $G^{\prime}=H^{\prime} *_{A} J$. Thus, elements from $G^{\prime}$ (resp. $G_{i}$ ) can be represented by elements from $\operatorname{Red}\left(H^{\prime}, J\right)\left(\right.$ resp. $\left.\operatorname{Red}\left(H_{i}, J\right)\right)$. Let $k \notin G^{\prime}$ be a new constant, let $f \in \operatorname{In}$, and let $\widetilde{w}=\left(w_{1}, \ldots, w_{N}\right)$, where $w_{i} \in \operatorname{Red}(H, J)$ is a reduced $(H, J)$-sequence. Recall from Section 4.1 that we view $\operatorname{Red}(F, J)$ (where $F$ is some base group) as a relational structure equipped with the multiplication in the base groups $F$ and $J$ and the concatenation and inversion of reduced $(F, J)$-sequences.

Lemma 4.8. Let $\chi\left(x, y_{1}, \ldots, y_{m}, \widetilde{z}\right)$ be a (not necessarily positive) boolean formula over the signature of the structure $\operatorname{Red}\left(H^{\prime}, J\right)$ and with constants from $\operatorname{Red}(H, J)$. If

$$
\forall x \in\{u \in \operatorname{Red}(H, J) \mid \operatorname{act}[u, X]=f\} \exists y_{1} \cdots \exists y_{m}\left\{\begin{array}{l}
\bigwedge_{1 \leq i \leq m} y_{i} \in \operatorname{Red}\left(H_{i}, J\right) \\
\wedge \chi\left(x, y_{1}, \ldots, y_{m}, \widetilde{w}\right)
\end{array}\right\}
$$

in $\operatorname{Red}\left(H^{\prime}, J\right)$, then there are $v_{1}, v_{2} \in \operatorname{Red}(H, J)$ with act $\left[v_{1}, X\right] \circ f \circ \operatorname{act}\left[v_{2}, X\right]=$ $f$ and

$$
\exists y_{1} \cdots \exists y_{m}\left\{\begin{array}{l}
\bigwedge_{1 \leq i \leq m} y_{i} \in \operatorname{Red}\left(\left(H_{i}\right)_{k}^{f}, J\right) \\
\wedge \chi\left(v_{1} \cdot k \cdot v_{2}, y_{1}, \ldots, y_{m}, \widetilde{w}\right)
\end{array}\right\} \quad i n \operatorname{Red}\left(\left(H^{\prime}\right)_{k}^{f}, J\right)
$$

Remark 4.9. The reader may observe some asymmetry in the above consideration: We put the new generator $k$ into the left factor (which is initially $H$ ) of the amalgamated free product. But this is an arbitrary choice. If $G_{1}$ and $G_{2}$ are groups such that $G_{1} \cap G_{2}=A$ is a subgroup of $G_{1}$ and $G_{2}, X \leq A$, and $f$ is an automorphism of $X$, then $\left(G_{1}\right)_{k}^{f} *_{A} G_{2}=G_{1} *_{A}\left(G_{2}\right)_{k}^{f}$. In particular, in Theorem 4.7 one gets $G_{k_{1}, \ldots, k_{i}}^{f_{1}, \ldots, f_{i}} \simeq H_{k_{1}, \ldots, k_{i}}^{f_{1}, \ldots, f_{i}} *_{A} J \simeq H *_{A} J_{k_{1}, \ldots, k_{i}}^{f_{1}, \ldots, f_{i}}$.

### 4.4 Proof of Lemma 4.8

The following data were already fixed:

- the finite normal subgroup $X \leq A$ and the elements $s_{\alpha \beta}$ from Lemma 4.4
- $f \in \operatorname{In}$
- the sets $\operatorname{Red}(H, J) \subseteq \operatorname{Red}\left(H_{i}, J\right) \subseteq \operatorname{Red}\left(H^{\prime}, J\right) \subseteq \operatorname{Red}\left(\left(H^{\prime}\right)_{k}^{f}, J\right)$ of reduced sequences from Section 4.3
- elements $w_{1}, \ldots, w_{N} \in \operatorname{Red}(H, J)$ from Section 4.3

Moreover, let us fix a (not necessarily positive) boolean formula $\chi\left(x, y_{1}, \ldots, y_{m}, \widetilde{z}\right)$ over the signature of the structure $\operatorname{Red}\left(H^{\prime}, J\right)$. Thus, $\chi$ is a boolean combination of propositions of the form $x \cdot y \sim z, x \sim y^{-1}$, and $x y=z$ in the base group $H^{\prime}$ or $J$, where $x, y$, and $z$ are either variables or constants from $\operatorname{Red}\left(H^{\prime}, J\right)$. Let $W$ be the union of $\left\{w_{1}, \ldots, w_{N}\right\}$ and the set of all constants appearing in $\chi$ and let $d$ be the number of atomic propositions of the form $x \cdot y \sim z$ that occur in $\chi$. Choose a number $\lambda>2 d$ such that $|X|$ ! divides $\lambda-1$. Finally, choose an element $x_{f} \in \operatorname{Red}(H, J)$ such that $\operatorname{act}\left[x_{f}, X\right]=f$, which exists since $f \in \operatorname{In}$. By appending, if necessary, suitable sequences $s_{\alpha \beta}$ to the left (right) of $x_{f}$, we may w.l.o.g. assume that $x_{f}=(H \backslash A) \cdot \operatorname{Red}(H, J) \cdot(H \backslash A)$.

Fix an element $h \in H \backslash A$ and two elements $j_{0}, j_{1} \in J \backslash A$ with $j_{1} \notin j_{0} A$. Since we assume that $[J: A] \geq 3, j_{0}$ and $j_{1}$ exist.

A $J$-system of degree $n(n \geq 2)$ is a tuple $\mathcal{R}=\left(r_{0}, \ldots, r_{\lambda}\right)$ with

$$
r_{i} \in\left\{\left(h j_{0}\right)^{|X|!},\left(h j_{1}\right)^{|X|!}\right\}^{n} .
$$

There are $2^{n(\lambda+1)} J$-systems of degree $n$. Note that $r_{i-1} s_{H J} x_{f} s_{J J} r_{i} \in \operatorname{Red}(H, J)$. The $J$-system $\mathcal{R}=\left(r_{0}, \ldots, r_{\lambda}\right)$ has no long overlapping, if for all $0 \leq i, j \leq \lambda$ and all $\alpha, \beta \in\{1,-1\}$ we have: ${ }^{4}$ if $r_{i}^{\alpha}=u_{1} \cdot u_{2}, r_{j}^{\beta}=v_{1} \cdot v_{2},\left|u_{2}\right|=\left|v_{1}\right| \geq$ $\frac{\left|r_{i}\right|-\left|s_{H J} x_{f} s_{J J}\right|}{2}$, and there exist $a, b \in A$ with $a v_{1}=u_{2} b$ in $G$, then: $u_{1}=v_{2}=\varepsilon$, $i=j$, and $\alpha=\beta$.

The next lemma follows immediately from the previous definition:
Lemma 4.10. Assume that $\mathcal{R}$ has no long overlapping. If

$$
\left(r_{i-1} s_{H J} x_{f} s_{J J} r_{i}\right)^{\alpha} \sim p \cdot r_{j}^{\beta} \cdot q
$$

for $p, q \in \operatorname{Red}(H, J)$ and $\alpha, \beta \in\{1,-1\}$, then either $p=\varepsilon$ or $q=\varepsilon$, i.e., $r_{j}^{\beta}$ cannot be properly contained in a segment which is opposite to a segment $\left(r_{i-1} s_{H J} x_{f} s_{J J} r_{i}\right)^{\alpha}$ in a diagram.

Note the difference between the definition of a $J$-system without long overlappings and a $t$-system without long overlappings in Section 3.4. For $t$-systems we formulated the restrictions concerning overlappings in terms of the projections $\pi_{t}\left(r_{i}^{\alpha}\right)(\alpha \in\{1,-1\})$. One might think that for $J$-systems we may use the projections of the sequences $r_{i}^{\alpha}$ onto the letters $j_{i}^{\alpha}(\alpha \in\{1,-1\}, i \in\{0,1\})$. But this would not work. For reduced $t$-sequences, it was crucial that $u \sim v$ implies $\pi_{t}(u)=\pi_{t}(v)$. A corresponding property for reduced $(H, J)$-sequences does not hold: for instance, for every choice of $j_{0} \in J \backslash A$ above, we may have $j_{0}^{-1} \in A j_{0} A$.

[^3]Hence we may have $j_{0} \sim j_{0}^{-1}$. Therefore, in the above definition, we have to exclude long overlappings by directly forbidding certain Van Kampen diagrams in order to obtain Lemma 4.10: Note that excluding an identity $a v_{1}=u_{2} b$ in the group $G$ (with $u_{2}$ a "long" suffix of some $r_{i}^{\alpha}$ and $v_{1}$ a "long" prefix of some $r_{j}^{\beta}$ ), means that we exclude the existence of a Van Kampen diagram of the following form:

For reduced $t$-sequences, in order to exclude such a diagram, one only has to require $\pi_{t}\left(u_{2}\right) \neq \pi_{t}\left(v_{1}\right)$. Nevertheless, thanks to the finiteness of $A$, we can prove the existence of $J$-systems (of sufficiently high degree) without long overlapping:

Lemma 4.11. There exists $n_{0}$ (depending only on $\lambda$ ) such that for all $n \geq n_{0}$ there exists a J-system of degree $n$ without long overlapping.

Proof. Analogously to the proof of Lemma 3.15 it suffices to show that if the $J$-system $\mathcal{R}=\left(r_{0}, \ldots, r_{\lambda}\right)$ has a long overlapping, then it can be described with strictly less than $n(\lambda+1)$ bits. Again, we distinguish four cases:
Case 1: for some $\alpha \in\{1,-1\}$ and some $0 \leq i, j \leq \lambda$ with $i \neq j, r_{i}^{\alpha}$ and $r_{j}^{\alpha}$ have a long overlapping. Thus, assume that $r_{i}^{\alpha}=u_{1} \cdot u_{2}, r_{j}^{\alpha}=v_{1} \cdot v_{2}$, $\left|u_{2}\right|=\left|v_{1}\right| \geq \frac{\left|r_{i}\right|-\left|s_{H J} x_{f} s_{J J}\right|}{2}$, and $a v_{1}=u_{2} b$ in $G$ for some $a, b \in A$. W.l.o.g. assume that $\alpha=1$. We first claim that the sequence $v_{1}$ can be reconstructed from the sequence $u_{2}$, and $a \in A$ : We know that $v_{1} \in \operatorname{Red}(H, J)$ is a sequence over the letter $h, j_{0}, j_{1}$. Assume that $w \in \operatorname{Red}(H, J)$ is a sequence over the letters $h, j_{0}, j_{1}$ such that $a w=u_{2} c$ in $G$ for some $c \in A$. Thus, $v_{1}=w\left(c^{-1} b\right)$ in $G$. This implies $\left|v_{1}\right|=|w|$. We have to show that $v_{1}=w$ (as reduced $(H, J)$-sequences). We prove this by induction over $\left|v_{1}\right|=|w|$. If $\left|v_{1}\right|=0$, then $v_{1}=\varepsilon=w$. If $v_{1}=h \cdot v^{\prime}$, then we must have also $w=h \cdot w^{\prime}$ for some sequence $w^{\prime}$. It follows $v^{\prime}=w^{\prime}\left(c^{-1} b\right)$ in $G$. Inductively we obtain $v^{\prime}=w^{\prime}$ and thus $v_{1}=w$. Now assume that (w.l.o.g.) $v_{1}=j_{0} \cdot v^{\prime}$. If also $w=j_{0} \cdot w^{\prime}$ for some $w^{\prime}$, then we can conclude as above. Hence, assume that $w=j_{1} \cdot w^{\prime}$. We obtain a Van Kampen diagram of the following form, where $a^{\prime} \in A$ :

Thus, $j_{1} \in j_{0} A$, which contradicts our choice for $j_{0}$ and $j_{1}$.
From the above consideration, it follows that $r_{j}$ can be reconstructed from the triple ( $i, a, v_{2}$ ) (note that the length of $v_{1}$ can be calculated from $\left|v_{2}\right|$ ). Hence, in the description of $\mathcal{R}$ we can save at least $\frac{\left|r_{i}\right|-\left|s_{H J} x_{f} s_{J J}\right|}{2} \frac{1}{2|X|!}-O(\lambda+|A|)=$
$\frac{2 n|X|!-\left|s_{H J} x_{f} s_{J J J}\right|}{2} \cdot \frac{1}{2|X|!}-O(1)=\frac{n}{2}-O(1)$ many bits. For a sufficiently large $n$, this term is strictly greater than 0 ; note that $\left|s_{H J} x_{f} s_{J J}\right|, \lambda$, and $|A|$ are constants.

Case 2: for some $0 \leq i \leq \lambda, r_{i}$ has a long overlapping with itself. Thus, assume that $r_{i}=u_{1} \cdot u^{\prime}=v_{1} \cdot v_{2},\left|u^{\prime}\right|=\left|v_{1}\right| \geq \frac{\left|r_{i}\right|-\left|s_{H J} x_{f} s_{J J}\right|}{2}$, and $a v_{1}=u^{\prime} b$ in $G$ for some $a, b \in A$, see the following diagram:

It follows that there exists $p>1$, a factorization $r_{i}=u_{1} \cdot u_{2} \cdots u_{p}$, and $a_{1}, \ldots, a_{p} \in A$ (we have $a_{1}=a$ and $a_{p}=b$ ) such that

- $\left|u_{1}\right|=\left|u_{2}\right|=\cdots\left|u_{p-1}\right| \geq\left|u_{p}\right|$,
- $a_{i-1} u_{i-1}=u_{i} a_{i}$ in $G$ for $1<i \leq p-1$, and
- $a_{p-1} w=u_{p} a_{p}$ in $G$, where $w$ is the prefix of $u_{p-1}$ of length $\left|u_{p}\right|$,
see also the following diagram:

We claim that $r_{i}$ can be reconstructed from the pair ( $u_{1}, a_{1}$ ): First, $u_{1}$ and $a_{1}$ determine $u_{2}$. The idea is the same as in Case 1. If $x \in \operatorname{Red}(H, J)$ is a sequence over the letters $h, j_{0}, j_{1}$ with $a_{1} u_{1}=x c$ in $G$ (for some $c \in A$ ), then $x c=u_{2} a_{2}$, i.e., $u_{2}=x\left(c a_{2}^{-1}\right)$ in $G$. We then obtain $u_{2}=x$ as in Case 1. Next from $u_{1}, u_{2}$, and $a_{1}$ we can determine $a_{2} \in A$ by the equation $a_{1} u_{1}=u_{2} a_{2}$. Having $u_{2}$ and $a_{2}$ available, we can determine $u_{3}$. We continue in this way.

By the previous paragraph, in the description of $\mathcal{R}$ we can save at least $\frac{\left|r_{i}\right|-\left|s_{H J} x_{f} s_{J J}\right|}{2} \frac{1}{2|X|!}-O(1)=\frac{n}{2}-O(1)$ many bits.
Case 3: for some $0 \leq i, j \leq \lambda$ with $i \neq j, r_{i}$ and $r_{j}^{-1}$ have a long overlapping. This case is analogous to Case 1.
Case 4: for some $0 \leq i \leq \lambda, r_{i}$ and $r_{i}^{-1}$ have a long overlapping. Hence, $r_{i}=u_{1} \cdot u_{2}, r_{i}^{-1}=v_{1} \cdot v_{2},\left|u_{2}\right|=\left|v_{1}\right| \geq \frac{\left|r_{i}\right|-\left|s_{H J} x_{f} s_{J J}\right|}{2}$, and $a v_{1}=u_{2} b$ in $G$ for some $a, b \in A$. Thus, we have a diagram of the following form:

From $r_{i}^{-1}=v_{1} \cdot v_{2}$ we get $r_{i}=v_{2}^{-1} \cdot v_{1}^{-1}=u_{1} \cdot u_{2}$. With $\left|u_{2}\right|=\left|v_{1}\right|=\left|v_{1}^{-1}\right|$ we get $v_{1}=u_{2}^{-1}$, i.e., $a u_{2}^{-1}=u_{2} b$ in $G$. Assume that $\left|u_{2}\right|$ is even (the case that $\left|u_{2}\right|$ is odd is similar) and write $u_{2}=w_{1} \cdot w_{2}$ with $\left|w_{1}\right|=\left|w_{2}\right|$. Thus, the above diagram looks as follows:

But then we can shorten the description of $\mathcal{R}$ to less than $n(\lambda+1)$ bits as follows: Instead of writing down $r_{i}$ using $n$ bits, we write down the triple $\left(u_{1}, w_{1}, a\right)$. From $w_{1}$ and $a$ we can reconstruct $w_{2}^{-1}$ in the same way as $v_{1}$ was reconstructed from $u_{2}$ and $a$ in Case 1. This saves at least $\frac{\left|u_{2}\right|}{2} \cdot \frac{1}{2|X|!}-O(1) \geq \frac{\left|r_{i}\right|-\left|s_{H J} x_{f} s_{J J}\right|}{4}$. $\frac{1}{2|X|!}-O(1)=\frac{n}{4}-O(1)$ many bits.

The proof of Lemma 4.11 is the only place, where we need the assumption that $A$ is finite.

Remark 4.12. With some other restrictions on $J$ and $A$, we can prove the existence of a J-system without long overlapping also in the case that $A$ is not necessarily finite. Recall that a double coset of $A$ in $J$ is a set of the form AjA for some $j \in J$. The group $J$ can be partitioned into double cosets of $A$. Now assume for a moment that there are at least three double cosets of $A$ in $J$. Clearly, $A$ is one of them. If follows that we can choose $j_{0}, j_{1} \in J$ such that (i) $j_{0}, j_{1} \notin A$ and (ii) $j_{1} \notin A j_{0} A$. With these restrictions, it is not difficult to prove again the existence of a J-system without long overlapping. The proof is similar to the proof of Lemma 4.11. One only has to notice that in each of the four cases, we never have to specify an element from the subgroup $A$ in order to reduce the size of the description of the $J$-system $\mathcal{R}$. Since the finiteness of $A$ was only used in the proof of Lemma 4.11, it follows together with the weaker restrictions (17), which where sufficient in order to prove the main Lemma 4.4 from Section 4.2, that $\mathrm{Th}_{+}(G)$ can be reduced to $\mathrm{Th}_{\exists}(G)$ also in case one of the following restrictions hold for $G=H *_{A} J$ :

- $[H: A]=[J: A]=2$ or
- A has at least three double cosets in $H$ (this implies that $[H: A] \geq 3$ ) and $\exists j \in J \backslash A: A \cap j A j^{-1}$ finite or
- A has at least three double cosets in $J$ (this implies that $[J: A] \geq 3$ ) and $\exists h \in H \backslash A: A \cap h A h^{-1}$ finite.

Let us fix a $J$-system $\mathcal{R}=\left(r_{0}, \ldots, r_{\lambda}\right)$ of degree $n$ without long overlapping, where moreover $\left|r_{i-1} s_{H J} x_{f} s_{J J} r_{i}\right|>|w|$ for all $w \in W$. For $1 \leq i \leq \lambda$, $u, v \in \operatorname{Red}\left(\left(H^{\prime}\right)_{k}^{f}, J\right)$, and $0 \leq j \leq|u|$ we write $u \xrightarrow{j}_{i} v$ if there exist $u_{1}, u_{2} \in$ $\operatorname{Red}\left(\left(H^{\prime}\right)_{k}^{f}, J\right)$ and $\alpha \in\{1,-1\}$ such that

- $u=u_{1} \cdot\left(r_{i-1} s_{H J} x_{f} s_{J J} r_{i}\right)^{\alpha} \cdot u_{2}$,
- $v=u_{1} \cdot\left(r_{i-1} s_{H J} k s_{J J} r_{i}\right)^{\alpha} \cdot u_{2}$, and
- $\left|u_{1}\right|=j$

We write $u \Rightarrow_{i} v$ if there exist $u^{\prime}, v^{\prime} \in \operatorname{Red}\left(\left(H^{\prime}\right)_{k}^{f}, J\right)$ and $0 \leq j \leq|u|=\left|u^{\prime}\right|$ such that $u \sim u^{\prime} \stackrel{j}{\rightarrow}_{i} v^{\prime} \sim v$. Clearly, the relation $\Rightarrow_{i}$ is terminating. Let $\operatorname{IRR}_{i}=\left\{u \mid \neg \exists v: u \Rightarrow_{i} v\right\}$. Note that $W \subseteq \operatorname{IRR}_{i}$ by the choice of $n$, Moreover, $s \Rightarrow_{i} t$ implies also $s^{-1} \Rightarrow_{i} t^{-1}$.

The next four lemmas can be shown analogously to the corresponding lemmas in Section 3.4.
 that $u \sim w$ or there exists $p \in \operatorname{Red}\left(\left(H^{\prime}\right)_{k}^{f}, J\right)$ such that $u \stackrel{*}{\Rightarrow}{ }_{i} p_{i} \stackrel{*}{\Leftarrow} w$.

The previous lemma implies that for every $1 \leq i \leq \lambda$ and every sequence $u \in \operatorname{Red}\left(\left(H^{\prime}\right)_{k}^{f}, J\right)$, if $u \stackrel{*}{\Rightarrow}_{i} v \in \operatorname{IRR}_{i}$ and $u \stackrel{*}{\Rightarrow}_{i} w \in \operatorname{IRR}_{i}$, then $v \sim w$. Let $\mathrm{NF}_{i}(u)$ denote an arbitrary sequence with $u \stackrel{*}{\Rightarrow}{ }_{i} \mathrm{NF}_{i}(u) \in \mathrm{IRR}_{i}$; it is unique up to $\sim$. Note that if the concatenation $u \cdot v$ of $u$ and $v$ is defined then also the concatenation $\mathrm{NF}_{i}(u) \cdot \mathrm{NF}_{i}(v)$ is defined.

Lemma 4.14. For all $1 \leq i \leq \lambda$ we have:

- $\mathrm{NF}_{i}(w) \sim w$ for all $w \in W$,
- if $u \sim v^{-1}$ for $u, v \in \operatorname{Red}\left(H^{\prime}, J\right)$, then $\mathrm{NF}_{i}(u) \sim \mathrm{NF}_{i}(v)^{-1}$.

Lemma 4.15. Let $v, w \in \operatorname{Red}\left(H^{\prime}, J\right)$ such that $v \cdot w$ is defined (as a reduced $\left(H^{\prime}, J\right)$-sequence $)$. There are at most two $i \in\{1, \ldots, \lambda\}$ with $\mathrm{NF}_{i}(v) \cdot \mathrm{NF}_{i}(w) \nsim$ $\mathrm{NF}_{i}(v \cdot w)$.

Lemma 4.16. Let $x_{j}, y_{j}, z_{j} \in \operatorname{Red}\left(H^{\prime}, J\right)$ for $1 \leq j \leq d$. Then there exists $1 \leq i \leq \lambda$ such that for all $1 \leq j \leq d, x_{j} \cdot y_{j} \sim z_{j}$ if and only if $\mathrm{NF}_{i}\left(x_{j}\right)$. $\mathrm{NF}_{i}\left(y_{j}\right) \sim \mathrm{NF}_{i}\left(z_{j}\right)$.
Now, Lemma 4.8 can be shown analogously to Lemma 3.13: Assume that

$$
\forall x \in\{s \in \operatorname{Red}(H, J) \mid \operatorname{act}[s, X]=f\} \exists y_{1} \cdots \exists y_{m}\left\{\begin{array}{l}
\bigwedge_{1 \leq i \leq m} y_{i} \in \operatorname{Red}\left(H_{i}, J\right) \\
\wedge \chi\left(x, y_{1}, \ldots, y_{m}, \widetilde{w}\right)
\end{array}\right\}
$$

in $\operatorname{Red}\left(H^{\prime}, J\right)$. Let

$$
s=r_{0} s_{H J} x_{f} s_{J J} r_{1} s_{H J} x_{f} s_{J J} r_{2} \cdots s_{H J} x_{f} s_{J J} r_{\lambda-1} s_{H J} x_{f} s_{J J} r_{\lambda} \in \operatorname{Red}(H, J)
$$

Note that $\operatorname{act}[s, X]=\operatorname{act}\left[x_{f}, X\right]^{\lambda}=\operatorname{act}\left[x_{f}, X\right]=f$ since $\lambda-1$ is a multiple of $|X|$ !. Thus, there exist sequences $t_{i} \in \operatorname{Red}\left(H_{i}, J\right), 1 \leq i \leq m$, with $\chi\left(s, t_{1}, \ldots, t_{m}, \widetilde{w}\right)$ in $\operatorname{Red}\left(H^{\prime}, J\right)$. By Lemma 4.14 and Lemma 4.16 there exists $1 \leq j \leq \lambda$ such that $\chi\left(\mathrm{NF}_{j}(s), \mathrm{NF}_{j}\left(t_{1}\right), \ldots, \mathrm{NF}_{j}\left(t_{m}\right), \widetilde{w}\right)$ in $\operatorname{Red}\left(\left(H^{\prime}\right)_{k}^{f}, J\right)$. Since
$\mathcal{R}$ has no long overlapping, there exists exactly one occurrence of $r_{j-1} s_{H J} x_{f} s_{J J} r_{j}$ in every sequence which is $\sim$-equivalent to $s$. Hence, we can write $s=v_{1} \cdot x_{f} \cdot v_{2}$ and $\mathrm{NF}_{j}(s) \sim v_{1} \cdot k \cdot v_{2}$ for some $v_{1}, v_{2} \in \operatorname{Red}(H, J)$. Thus,

$$
\begin{aligned}
f=\operatorname{act}[s, X] & =\operatorname{act}\left[v_{1} \cdot x_{f} \cdot v_{2}, X\right]= \\
& \operatorname{act}\left[v_{1}, X\right] \circ \operatorname{act}\left[x_{f}, X\right] \circ \operatorname{act}\left[v_{2}, X\right]=\operatorname{act}\left[v_{1}, X\right] \circ f \circ \operatorname{act}\left[v_{2}, X\right]
\end{aligned}
$$

and

$$
\exists y_{1} \cdots \exists y_{m}\left\{\begin{array}{l}
\bigwedge_{1 \leq i \leq m} y_{i} \in \operatorname{Red}\left(\left(H_{i}\right)_{k}^{f}, J\right) \\
\wedge \chi\left(v_{1} \cdot k \cdot v_{2}, y_{1}, \ldots, y_{m}, \widetilde{w}\right)
\end{array}\right\} \quad \operatorname{in} \operatorname{Red}\left(\left(H^{\prime}\right)_{k}^{f}, J\right)
$$

This finishes the proof of Lemma 4.8.

## 5 Applications

The number of ends of a group $G$ is, roughly speaking, the maximal number of connected components in the Cayley-graph of $G$ which can be obtained by removing an arbitrary finite set of nodes, see e.g. [4] for more details. It is well known that the number of ends of $G$ is either 1,2 , or $\infty$. Moreover, a famous result of Stallings states that a group $G$ has more than one end if and only if it can be written as $G=H *_{A} J$ or $G=\left\langle H, t ; t^{-1} a t=\varphi(a)(a \in A)\right\rangle$ with $A$ finite [24]. Hence we obtain:

Theorem 5.1. If the group $G$ has more than one end and $\operatorname{Th}_{\exists+}(G)$ is decidable, then $\mathrm{Th}_{+}(G)$ is decidable.

Recall that a group is virtually free if it has a free subgroup of finite index. Every virtually-free group has more than one end. Moreover, in [13], we have shown that every virtually-free group has a decidable existential theory. Thus, Theorem 5.1 implies:

Theorem 5.2. Let $G$ be a virtually-free group. Then $\operatorname{Th}_{+}(G)$ is decidable.
In $[20,23]$, it is shown that the existential theory of a torsion-free hyperbolic group is decidable. Again, with Theorem 5.1 we get:

Theorem 5.3. Let $G$ be a torsion-free hyperbolic group. If $G$ has more than one end, then $\mathrm{Th}_{+}(G)$ is decidable.

It should be noted that the statements of Theorem 5.2 and Theorem 5.3 are orthogonal: By a result of Stallings [24], a torsion-free virtually-free group is already free.

## 6 Open problems

We presented quite general conditions under which the positive theory of a group $G$ can be reduced to the existential theory of $G$. To the knowledge of the authors there is currently no example of a group $G$ such that the existential theory of $G$ is decidable but the positive theory of $G$ is undecidable. The decidability of the positive theory of a virtually-free group leads of course to the question, whether the full first-order theory of a virtually-free group is decidable. One might try to extend the techniques developed by Kharlampovich and Myasnikov in their solution of Tarski's problem about the theory of a free group [12] to the virtually-free case.

Underlying the definition of a $t$-system (resp. $J$-system) without long overlapping is a certain small cancellation condition. Similar conditions were also used in the construction of SQ-universal HNN-extensions [21] and amalgamated free products [22]. Recall that a group $G$ is SQ-universal if every countable group embedds into a quotient of $G$. One might ask, whether there is some relation between SQ-universality and the positive theory of a group.
